toward the end of their course. The relation between the average observed time and the standard is purely arbitrary. As each student is expected to equal or better the standard for each operation by the time he has completed the course, it would manifestly be unfair to set the standards as high as could be attained in a commercial laboratory, considering that the student is only required to spend the equivalent of 11 eight-hour days in the laboratory. On the other hand, the averages include many observations of students before they had reached their maximum efficiency, so that in general it is apparent that the standards can in most cases be placed below the averages, without injustice to the student. Therefore the standard time-intervals were chosen so that, in the opinion of the instructor, they could be attained by any student qualified for admission into the course (remembering that only graduate students are admitted) after proper instruction, and without spending an undue amount of time in the laboratory. Obviously, a great deal of work yet remains to be done to determine equitable standards.

During the period in which the studies were made the course was being given for the first time, and this method of instruction was just being developed. It is believed that as improvements are made in the laboratory and in the method of instruction, the unit time for many operations can easily be halved.

One of the interesting points brought out by these studies is the relation between filtering with one hand and with two hands. It is found that from 35 to 40% of the total time of pouring solutions from beakers into funnels is saved when both hands are used instead of one hand, without any apparent effect upon the accuracy of the manipulation. Consequently, the students are urged to acquire skill in simultaneous use of their hands in all cases of filtering where the nature of the precipitate does not require the use of stirring-rods for clean manipulation. The use of both hands applies to other phases of manipulation, such as transferring beakers on and off the hot plate and placing beakers under funnels.

It was ascertained early that considerable time could

Table 1—Observed and Standard Time of Various Laboratory Manipulations

No.	Operation	Minimum		Maximum		Average		Standard	
		min.	sec.	min.	sec.	min.	sec.	min.	sec.
1	Mixing samples	0	30.7	1	11.2	0	57.0	1	00
2	Weighing charges	0	47.3	1	49.1	1	11.2	1	00

16b	Ditto, duplicate	0	38.5	2	41.0	1	31.5	1	30
17a	Gravimetric weighing, first	1	31.3	2	20.0	1	56.5	2	00
17b	Ditto, duplicate	1	02.1	1	51.8	1	23.7	1	00

Less than 25 cc. of solution was used on all titrations included in tabulation. Figures include reading and recording.

be saved by modifying the filter-racks in such a way that the beakers containing solutions to be filtered could be placed back of the funnels and on the same level. This saves from 1.5 to 2 seconds for each pouring. The rack has several other advantages, not at present capable of translation into time-units, due to greater convenience in handling the beakers on the rack and under the funnels.

Another point is the relation between the use of dispensing burettes and graduates for adding portions of liquids to the assays. A direct comparison was made of the two methods with the same manipulator, adding 20 cc. of solution, accurate to the nearest 2 cc. The results were as follows:

a	With graduate, each portion.....	4.6 sec.
b	With burette, each portion.....	2.5 "
Time saved, each portion.....		2.1 sec.

By comparing *a* and *b* with No. 5 and No. 3 respectively in Table 1, it will be seen that the manipulator was faster than the average. The time saved with the burette would be much greater with a slower manipulator.

If it is necessary to fill the burette, the time required averages 22.3 sec., hence in this case there should be 11 or more assays in order to justify the use of the burette. If it is necessary to clean the burette, in addition to filling, this would add 34 sec., from which the time for cleaning the graduate, 12 sec., should be deducted, leaving a total of $(34 - 12) + 22.3 = 44.3$ sec. Thus the burette would not save time unless it were to be used for over 21 portions. As cleaning and filling of dispensing burettes in a commercial laboratory is one of the duties of the wash-boy, it is, of course, best to use the burettes for all solutions in common use, and to limit the graduate to those solutions used only, say, 8 or 10 times per day. This is common practice in laboratories that are well equipped and efficiently operated.

It is not possible at present to compare the time standards obtained by observation of students with those attained in commercial laboratories. A rough comparison was made by the instructor, who has had considerable experience in commercial laboratory practice. It was found that one or two of the students were able to equal the instructor's time on most unit operations, but would always lose time referring to notes, making false motions, and other items occasioned by inexperience.

ALL-DAY RUNS. It was found convenient to plot the results of all-day runs graphically in order to compare the work of different students. By plotting several runs on the same sheet, or by the use of tracing-paper, the comparisons can be made quickly, and the minimum time of each stage readily observed. When better data are obtained in the future, it is thought that a differential chart, showing the variations of each operation from a predetermined standard, will be more suitable than the charts now in use, which show the actual time for each group of manipulations.

The charts, as well as a tabulated summary of the day's work for each student are posted on the bulletin board. It has been found that such publicity is a great incentive to those students who are slower or less accurate than the

average to improve their work. From the charts and the tabulations, and by consultation with the instructor, the student can determine readily his weak points and focus his attention upon them when the next trial is made.

ACKNOWLEDGMENTS. I wish to acknowledge the helpful criticisms and hearty co-operation of Professors Theodore J. Hoover and James M. Hyde, not only in the preparation of this article, but also in the development of the time-study method of instruction in the laboratory.

Copper in Impure Sulphate Solution

By J. Ayrton Bradbury

*During leaching experiments on copper concentrate it was found desirable to devise a method of obtaining rapid and accurate copper assays on low-grade and impure sulphate solutions. It was essential that the method should be workable by manipulators with no chemical experience. The following was devised:

Pipette 10 cc. of solution into a 150-cc. beaker, add 5 cc. of 10% potassium iodide solution, stir occasionally, and allow to stand for about five minutes, until the precipitate of cuprous iodide settles. In cases of solutions containing less than 0.2 gm. copper per litre, a somewhat longer time may be necessary. Carefully filter through a 9-cm. filter paper, and wash twice with water to remove iron, cobalt, zinc, and magnesium sulphates. Place original beaker under the funnel, and pour over filter-paper 10 cc. of dilute (1:1) nitric acid, to dissolve the cuprous iodide precipitate. Allow to drain, wash once, but avoid undue dilution. Add 15 cc. (1:1 ammonia, transfer to colorimetric bottle, and dilute to the 35-cc. mark. Compare with standard scale of colors.

TO STANDARDIZE. To several lots of 10 cc. of impure solution, low in copper, add carefully measured quantities of cupric sulphate solution, sufficient to give amounts ranging from 0 to 2 gm. copper per litre. (Use a solution of cupric sulphate of which 1 cc. = 0.005 gm. copper, measuring from a burette.) Then carry each through the assay process, thus obtaining a standard set of colored solutions of equal bulks, namely, 35 cc. This method of standardizing necessarily removes errors caused by incomplete precipitation of cuprous iodide, although under the conditions of assay the precipitation of cuprous iodide has been found to be quantitative.

1. New standard colored solutions should be prepared whenever the constitution of the impure low-grade solution shows any great variation in analysis. Bottles containing standard solutions should be tightly stoppered.

2. Any greenish discoloration, due to the presence of ferrous salts after the addition of the ammonia, may be removed by oxidizing with a drop or two of hydrogen peroxide, followed, if necessary, by a second filtration. Such discoloration, however, should not occur if the conditions of assay are strictly observed.

3. Instead of applying the colorimetric test, the solution containing the ammonia may be titrated with dilute potassium cyanide solution.

Air-Lift in Theory and Practice

By A. W. Allen

INTRODUCTION. The increased popularity of the air-lift resulted from an appreciation of its simplicity and economy, and from a better understanding of underlying principles. The earlier interpretations of the theory of air-lifting have been proved erroneous; the respect shown for such ideas in preliminary design led to inefficiency and to a decreased utilization of the system. The simplest form of air-lifting is the vertical elevation of water through a pipe or other suitable channel. It was considered for a long time that the actual elevation of the water was caused by the upward pressure of a jet of air, and that the greater the force of air applied through this jet the more effective the result. The acceptance of this idea as a fundamental principle on which the lift operated led to a wasteful use of power and an unjustified condemnation of the system. The variation in result and the contradictory opinions expressed as to efficiency led to experimentation and large-scale tests, and these, in turn, to the discarding of the theory. As an alternative it was submitted and substantiated that the lifting was caused by the decrease in the specific gravity of the fluid, by admixture with air; and it was then realized that economical results could be obtained only by making this admixture thorough, that is, by spraying the air into the water over as great a surface as possible, and by regulating the flow of liquid so that friction would be reduced to the minimum. The applicability of the system was extended, and a higher efficiency was obtained as soon as these basic principles were understood. It was found that a satisfactory return could be obtained for power expended. The simplicity and low first-cost of the equipment needed, and the elasticity of the system when in operation, were favorable factors.

ESSENTIALS FOR AIR-LIFTING. A primary essential for economical air-lifting is that the depth of the sump must exceed the height to which it is required to elevate the liquid. The ratio of height to submergence varies with the height to which the fluid must be raised; but, in the case of the majority of lifts, up to 100 ft. or so, it is usually 1 to $1\frac{1}{2}$ or 2. If it be required to elevate the pulp or other liquid to a vertical distance of 20 ft., the sump, as the submerged part is called, should extend at least 30 ft. below the normal level of the fluid to be pumped. An ample depth of submergence, within obvious limits, is desirable; but the ratio is less in those cases where this is impracticable, and a decreased efficiency must be accepted as inevitable, or a compound lift must be erected. A fact that must be taken into consideration when depth of submergence is being considered is that greater depth means proportionately greater pressure of air. The system is so elastic that air-lifts often are used under conditions that lead to inefficient operation, and this, of course, is un-

desirable. A variation from the correct ratio is permissible, but any radical difference from the desirable proportions should be avoided.

DESIGN OF THE RISING-MAIN. Given a satisfactory depth of submergence, the next consideration is the design of the lift-pipe, commonly known as the rising-main. In the simple air-lift this may consist merely of a length of pipe of suitable dimensions, delivering into the bottom of a launder or sluice. This method of disposal is preferable to the use of a bend or elbow at the top of the rising-main, which is liable to cause a re-compression of the air after the lifting has been accomplished, thus absorbing power and doing no good. Moreover, the vertical and open discharge gives prompt indication of the wastefulness of unnecessary pressure or volume of air.

Air is delivered by one of a number of available methods, the simplest being by means of a small pipe lowered through the lift-pipe, the discharge in this case being sometimes effected through the right-angle arm of a T-piece. This method of supplying air is a simple one, and is especially suitable in the case where a slimed pulp is being lifted, the solid in which might settle and choke an air-pipe if the latter were arranged to deliver in an upward direction. The initial pressure of air required is the amount needed to overcome the hydrostatic head, or the weight of the fluid at the lowest point of submergence; this is approximately $\frac{1}{2}$ lb. per square inch per foot of depth of water, and proportionately more in the case of heavy liquids or pulps. This pressure, on account of the eductive action of the liquid being pumped, is reduced slightly as soon as operations are commenced. The air, as it rises in the lift-pipe, is increased in volume, thus accelerating the pumping action; when it reaches the discharge it should be allowed free egress and should meet with no restrictions. If no excessive pressure be used in the first instance, the air should escape at little above the pressure of the atmosphere; the discharge should be continuous and steady, rather than intermittent and jerky, the latter conditions arising from an imperfect mixture of air with liquid, or an excessive pressure or volume of air, all or any of which will result in poor achievement for power expended.

ELEVATING SOLIDS BY THE AIR-LIFT. Solids, whether in the form of the sandy or slimy constituents of a fluid pulp, can be elevated effectively and economically by means of the air-lift, and under a wide range of conditions. In this connection it possesses two particularly favorable mechanical features: there are no moving parts, and no packing-joints to be kept clean. Centrifugal pumps are used largely for such a purpose and generally are preferable in those cases where no disadvantage ensues from the dilution of the pulp with additional water

or solution. In some instances, particularly after dewatering, it is inadvisable to permit dilution, and diaphragm-pumps are used. In other cases the air-lift has been found to possess advantages that are absent in other types of pumps; it is not to be recommended, however, for the elevation of pulp containing heavy particles that, under conditions of normal fluidity, might segregate and cause chokage. To obviate failure from such a cause, an excessive velocity in the rising-main is sometimes ensured by the use of excess air, but this procedure is to be deprecated. The air-lift is not universally applicable to all purposes of elevation, and it is as well to recognize this fact.

ELASTICITY OF AIR-LIFT. For regular pumping from and to definite levels, next to the low first-cost and the fact that repairs and renewals are almost nil, the most favorable feature of an air-lift is its elasticity in regard to capacity. Temporary over-load may be met, within certain limits, by the increase in the volume of air; this, though not to be recommended in the case of continuous operation, may be considered as permissible in an occasional emergency for which regular and efficient provision would involve an unjustifiable expense. To arrange for the automatic control of both over-load and under-load, it is practicable to adopt a system whereby the supply of air depends on the height of the liquid in the sump, or submergence-pipe, from which the rising-main receives its supply. Fluctuations in delivery of material to the air-lift are adjusted immediately, and the amount of air used is regulated in strict proportion to the work done. This is a particularly advantageous feature where thickened sludge is being drawn from a number of settlers that are being tapped intermittently to permit of maximum dewatering. Minor fluctuations are likely in such a plant from time to time, and can be met satisfactorily without personal attention.

SUMMARY. The advantages and disadvantages of an air-lift may be summarized as follows: It is suitable (1) in the case where it is practicable to sink or to otherwise construct a well or sump to a depth exceeding the height required to lift the material; (2) where compressed air is available or can be produced at a reasonable cost; (3) where a pulp containing fine sand or slime must be elevated and where further dilution is undesirable; (4) where aeration would be beneficial, whether from the chemical or from the physical standpoint; (5) where the supply is intermittent, and where there are advantages to be gained by the adoption of a system capable of automatic and economical regulation of power; and (6) where low first cost is a primary consideration. The air-lift is unsuitable, or should be adopted with caution, in the case where (1) the height to which the liquid must be lifted is so great that an abnormal depth of sump would be required, and where it would be inadvisable to construct a compound lift; and (2) where the material to be elevated contains solid particles of a size and weight that would involve segregation from the liquid in the absence of excessive agitation, resulting in chokage of the air-pipe, of the rising-main, or of both.

Manganese

Probably about 95% of the world's production of manganese ores, manganiferous iron-ores (using the term broadly), and manganiferous zinc residuum is used directly or indirectly in the manufacture of iron and steel, the small percentage of true manganese ore not so consumed being used elsewhere, states a bulletin recently issued by the Imperial Mineral Resources Bureau. The greater part of the ore used in metallurgy is consumed in the making of the ferro-alloys required for steel production (ferro-manganese, spiegeleisen, silico-manganese, and silico-spiegel); the remainder—consisting wholly of manganiferous iron-ore—is used for the direct production of manganiferous pig-iron. Self-hardening steels, made before the development of high-speed tool steels, contained from $3\frac{1}{2}$ to 4% of manganese. Nickel-steels containing from 20 to 25% of nickel and 5 to 6% of manganese have been largely used, for many years, for electrical resistance-wires. The quantity of manganese consumed in the manufacture of manganese bronze, silver bronze, and other special alloys is relatively unimportant. The manganese bronze of commerce contains traces of manganese. The higher grades contain not more than 0.05% of manganese. The principal function of manganese in the ferro-manganese, or (as perhaps more usual in modern practice) the cupro-manganese added to the copper-zinc alloy, is to act as a deoxidizer. When ferro-manganese is employed, the small amount of iron thus introduced into the bronze is stated to increase appreciably the strength and toughness of the alloy, the most important use of which is in the manufacture of steamship propeller blades. Manganese dioxide is extensively used in the manufacture of dry-cell electric batteries, and for decolorizing glass—to which a slight amount of iron in the form of ferrous silicate gives a green tint. For decolorizing glass, from 2 to 15 lb. of manganese ore, of about the same high grade as that for dry-cell manufacture, is required per 1000 lb. of sand, a larger addition resulting in an amethyst tinge; if as much as 30 lb. be added, a black glass is produced. Manganese dioxide and salts prepared therefrom are extensively used as driers of paints in linseed or other drying oils, the quantity added to the oil being usually less than 0.5%. The dioxide is also employed in the manufacture of manganates and permanganates of sodium and potassium, used as disinfectants, for purifying various gases, and for other purposes. It has been extensively used in the manufacture of chlorine, but this gas is now obtained in the United Kingdom, the United States, and other large chlorine-producing countries almost entirely by electrolysis of either chloride of sodium or chloride of potassium. The dioxide is still used in some laboratories for the production of oxygen on a small scale. Manganese compounds are used to color glass, pottery, tiles, and bricks, in calico-printing and dyeing, and for certain paints (brown, green, and violet). Certain manganiferous ores from the weathered parts of silver-lead deposits are used as a flux in smelting lead and silver ores.

REVIEW OF MINING

MISSOURI SCHOOL OF MINES CELEBRATES ITS SEMI-CENTENARY AT ROLLA

The fiftieth anniversary of the Missouri School of Mines was celebrated on November 4 and 5, by a football match, an alumni banquet, and an address by T. A. Rickard. The toastmaster at the banquet was Arthur D. Terrell of the class of '98. The speakers included the present Director, Charles H. Fulton, and two former Directors, L. E. Young (1907-1913) and A. L. McKee (1915-1920). E. J. McCaustland, Dean of Engineering, spoke for the University of Missouri. Professor George R. Bean spoke for the present faculty, and was received with marked cordiality. He represented the class of '90. W. Y. Bean spoke for the class of '78, W. S. Thomas for that of '94, R. P. Cummins for '05, Ray F. Rucker for '06, R. R. Benedict for '08, V. H. McNutt for '10, J. K. Walsh for '17. Philip N. Moore, past president of the A. I. M. & M. E., spoke eloquently for the mining industry in its relation to the educational system typified by the 'M. S. M.' The proceedings were marked by the affectionate regard of the alumni for their alma mater and the recital of happy recollections of student days at Rolla. Next day Mr. Rickard delivered an address on 'The Education of the Mining Engineer'. Dean McCaustland transmitted the greetings of the University of Missouri. The occasion was dignified further by the presence of Bishop F. F. Johnson and the Rev. H. Nelson Tragitt, who delivered the invocation and benediction respectively. An excellent band from St. Louis diversified the program. The Director of the School, Charles H. Fulton, presided.

"HOPEFUL BUT NOT SANGUINE", SAYS D. C. JACKLING OF THE OUTLOOK FOR COPPER

D. C. Jackling was interviewed recently at Salt Lake City regarding the outlook for copper. Although he declared that he was no more optimistic than in August, an undertone of confidence was noted in his attitude.

When asked when production would probably be resumed, Mr. Jackling stated that this depended entirely upon the rate of consumption during the next few months. As soon as the surplus was reduced to an amount that would be sufficient to meet average consumption of three to four months, operations would be begun again. That is, he explained, if the average consumption was 100,000,000 or 125,000,000 lb. monthly, production would probably be resumed when the surplus reached a point near 300,000,000 to 400,000,000 lb. This amount must be kept on hand because a period of three to four months elapses before copper matte can be shipped from mines to refineries and made available for consumption. Prices, when resumption is begun, Mr. Jackling believes, must slowly return to those levels at which the metal sold before the War. No great foreign production hangs over the American market, he stated.

MERGER OF COAL AND STEEL ENTERPRISES IS PLANNED

Negotiations in San Francisco are virtually consummated looking to the consolidation of the Columbia Steel Co., the Southern California Iron & Steel Co., and the Utah Coal &

Coke Co. of Salt Lake City. Plans include the erection of a 500-ton blast-furnace in the vicinity of Salt Lake City for the smelting of iron ores obtained in Iron county; erection of a large coke-plant at Salt Lake City for by-products; development of the Utah Coal & Coke Co.'s properties; exploitation of the iron deposits near Iron Springs; working of limestone deposits near Salt Lake City, and the building of railroads to the new properties. In California it is planned to further enlarge the plants of the Columbia Steel Co. at Pittsburg and of the Southern California Steel company's properties.

Interested in the proposed merger are Wigginton E. Creed, of the Columbia Steel Co.; A. C. Denman, Jr., president of the Southern California Iron & Steel Co.; A. C. Ellis, Jr., president of the Utah Coke & Coal Co.; W. W. Armstrong, president of the National Copper Bank of Salt Lake City; and L. F. Rains.

BUNKER HILL SMELTER GETS ORE FROM BRITISH COLUMBIA

Lessees of the I. X. L. mine, at Rossland, B. C., recently shipped two tons of bonanza ore and 20 tons of second-grade ore to the Bunker Hill & Sullivan smelter, at Kellogg. The settlement on a former shipment of high-grade to the smelter at Trail, B. C., was made on a basis of 95% of the gold and silver content and \$100 for treatment, which, considering the grade of the ore—183.66 oz. per ton—the shippers thought excessive. They therefore have sent the last consignment to the B. H. & S. smelter. The Florence Silver Mining Co. is shipping 400 tons of concentrate and crude ore to the Bunker Hill & Sullivan smelter, which offers more satisfactory terms than Trail. This has been made possible by the recent reduction in freight-rates. The Florence ore is low in silver, the average of the present shipment being 20 oz. silver per ton and 60% lead, and therefore cannot stand high treatment-charges.

CHIEF CONSOLIDATED COMPANY ACQUIRES CONTROL OF ADDITIONAL PROPERTY AT EUREKA, UTAH

The Chief Consolidated Mining Co. has acquired control of the Eureka Lily Mining Co. and the East Tintic Mining Co., both of which are situated in the eastern end of the Tintic district. The Eureka Lily property adjoins the Tintic Standard mine, while the East Tintic company owns two blocks of ground that are divided by the Iron King holdings. At the annual meeting of the Eureka Lily stockholders on November 5 a new board of directors was elected, four of whom are officials of the Chief Consolidated; they are Walter Fitch, Cecil Fitch, L. B. Cripps, and Thomas Carmichael, while the fifth director is R. J. Evans, former president of the Eureka Lily. Acquisition of these two properties is in line with the policy of the Chief Consolidated to enlarge its holdings so as to perpetuate the company. The Chief company has built up one of the most successful mine organizations in the State, and it is known that its officials have taken a keen interest in the eastern part of the Tintic district ever since the Tintic Standard first found ore in 1915. It is reported that the Chief company has a substantial interest, if not control, in the Apex-Standard prop-

erty, which is situated in the eastern part of this district. For the three months ending October 18, the Water Lily shaft was sunk a distance of 1196.8 ft., or an average of 368.9 ft. per month. The shaft is now down to a depth of 1250 feet.

ALASKA

Hyder.—The Premier Gold Mining Co., recently made a shipment of \$15,000 worth of bullion, obtained from the second clean-up of the cyanide plant, and 200 tons of concentrate. The grade of the concentrate has not been announced, but if it runs as high as the last shipment the consignment should have a value of about \$350,000. Some 25 men are working on the ore-bunkers, at tide-water, preparatory to putting the tramway into operation.

ARIZONA

Jerome.—The United Verde Extension Copper Co. has distributed the dividend of 25c. payable to holders of stock of record at the close of business on October 10. A statement that accompanies the dividend says that the forces at the mine and smelter are still at the minimum but that the copper surplus had been reduced during the past six months to 9,796,000 lb. Development work has been restricted and no additional ore-reserves worthy of mention have been uncovered.—A recent announcement made by Robert E. Tally, assistant general manager for the United Verde Copper Co., indicates that additional men are to be added to the 275 men that are now employed at the mine and the 200 at the smelter. This increase will be necessitated by the starting of construction on the \$7,000,000 crushing and storage plant which will take two years to finish. The erection of the Cottrell plant is progressing and the smelter has been completely overhauled preparatory to resuming operations.

Kingman.—The No. 3 shaft of the United Eastern Mining Co. has reached a depth of 870 ft. and a station is being cut at the 850-ft. level preparatory to cross-cutting to pick up the vein. The shaft at the Big Jim mine has reached a depth of 670 ft. Pumps are now being installed and when this work is completed sinking is to be resumed.—The Tom Reed mill is handling better than 200 tons of ore per day. This production will be maintained for several weeks and will then be cut to 100 tons per day. The present policy will be to mill all ore that can be mined and milled at a profit even at the expense of reduced current tonnage. Recent work on the 400 and 600-ft. levels of the Aztec claim is reported to have opened some good ore. It is understood that development on the 700-ft. level has been disappointing although some good ore was found. The present high costs of mining make much of the Tom Reed 'ore' unprofitable; this was considered good ore prior to the War.

Recent samples taken from the Sunbeam mine assay as high as \$40 gold per ton. The Sunbeam property, it is understood, was recently taken over from Messrs. Burt and Probasco by the W. J. Loring Interests. Sampling at the mine is being continued preparatory to active development.

CALIFORNIA

Copper City.—Austen Bros., whose barium mine is near here, have closed a contract with San Francisco firms for 500 tons of ore per month, the product to be used in the manufacture of paint. An aerial tram carries the ore from the mine to the railway.

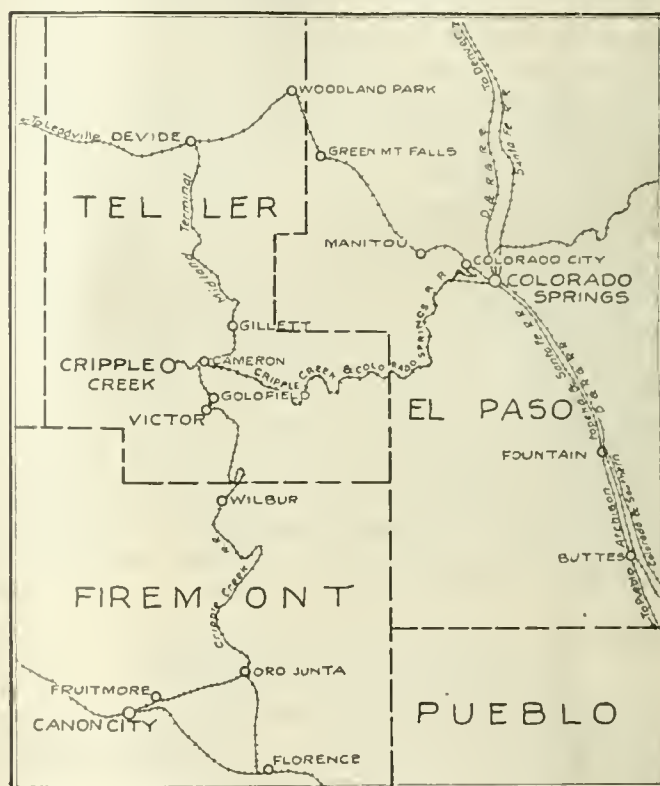

Engelmine.—All former records for production were broken by the Engels Copper Co. during October. Concentrate shipped contained 1,100,000 lb. of copper and 17,000 oz. of silver. According to E. E. Paxton, general manager, development in the lower levels of the mine are highly satisfactory.

Grass Valley.—According to T. R. Pell, plans for the con-

solidation of the Central Consolidated Mines, Inc., and the Norambagua property have been consummated. Some 2000 acres of mineral land will as a result come into the possession of the Banner Consolidated Mines, Inc., as the new company is called. The Norambagua property is three miles south of Grass Valley, and the Central Consolidated is north-east of the town. Neither has been operated for some years. John M. Nicol, of San Francisco, is in charge of operations.

The wage-scale agreement between the Mine Workers Protective League and four of the leading mining companies has been formally signed and is now in effect. It provides for a basic wage scale of \$4.25 per day for machine miners and \$3.78 per day for shovelers with extra pay for special work and for overtime. The companies signing the agreement are the Empire Mines Co., the North Star Mines Co., the Sultana Mining Co., and the Idaho-Maryland Mining Co.

Nevada City.—High-grade gold ore is reported to have been found in the east drift of the Red Ledge mine. C. C.

Central Colorado

Greenwood, superintendent, has been exploring the property for some months.

Placerville.—The California State Railway Commission has ordered the Eldorado Water Co. and the Western States Gas & Electric Co. to deliver to the Pacific Channel mine, operated by John F. Sexton, 40 miner's inches of water for 24 hours every third day. This will permit operation of the mine one 8-hr. shift each day. It is expected that other mines in the vicinity will be opened as a result of the ruling. The question involved was the amount of water dedicated to mining use, and it was found by the Commission that, under the terms of the contract between the Western States and the Eldorado company, 200 miner's inches are stipulated to be for mining use.

Plymouth.—At the Plymouth Consolidated mine high-grade gold ore has been found in the small west vein on the 3225-ft. level. A raise is now being driven to connect with the 3050-ft. level. W. J. Loring expresses the opinion that operations from now on will return a profit.

Sutter Creek.—A. S. Howe, superintendent, reports that the work of sinking the shaft of the Central Eureka mine is progressing satisfactorily, that during the past week the shaft was sunk 16 ft. The contract, which calls for the sinking of the shaft 200 ft., will be completed within two weeks.

COLORADO

Blackhawk.—Returns received on ore from the Black Jack mine, shipped to the smelter by the Silver Mountain Mining Co., showed 0.27 oz. gold, 82.85 oz. silver, and 12.68% lead, total value \$91.79 per ton. Another car from the Wheeler tunnel shipped by the same company gave returns of 0.32 oz. gold, 53.20 oz. silver, and 8.25% lead. The company has ore ready to ship at both properties and assays indicate a higher value in both consignments.

Boulder.—Lessees on the Caribou are shipping silver ore ranging from \$100 to \$1000 per ton; with a dozen lessees shipping, the 1921 production should show considerable increase.—Lessees on the Yellow Pine are shipping a good grade of ore and steady production will shortly start from the Potosi and Grand County mines.—Ore sampling 100

Durango.—The power-house, with electrical and compressor plants at the May Day mine, was totally destroyed by fire of unknown origin Sunday night, November 6. The loss is estimated at \$10,000, insurance unknown. No plans have been announced as to re-construction. It had been planned to operate the mine during the winter.

Idaho Springs.—A new flume is being laid to the Mattie mine and, as soon as water can be turned in, development is to be commenced by a new company recently organized.

IDAHO

Bayview.—The owners of the Moonlight group have found rich silver ore that assays \$120 per ton, besides some gold. There is said to be at least 100 tons of this rich ore.

Coeur d'Alene.—High-grade ore has been found on the property of the Lookout Mountain Mining & Milling Co., on Pine creek. The size of the body has not been determined, but a cross-cut to the vein disclosed 8 ft. of ore with the wall unreached. The ore is of smelting grade, assaying 30 oz. silver and 30% lead. The scene of the disclosure is at a depth of 300 ft., reached by a cross-cut 600 ft. long from

The Water-Front at Hyder, Alaska

oz. silver is reported recently opened up at Salina; it is being prepared for shipment.

Breckenridge.—The Tymos, June Bug, Monte Cristo, and North Star properties have laid in supplies and will continue operating through the winter.—The dredges of the Tonopah Placers Co. and the Blue River Placers Co. will continue operations during the winter. A shipment of bullion was sent the U. S. Mint in Denver by the Tonopah company last week.

Cripple Creek.—Operations have been resumed on company account by the El Paso Consolidated company, and new ground is to be exploited below the 800-ft. level. A number of lessees are at work.

The Banner Gold, Henry Adney, and C. K. & N. mines, former producers and properties adjacent to the El Paso, have been leased to a company headed by Robert Hasty, a successful lessee of the district with outside backing, and as soon as the machinery is overhauled operations will start underground.

Denver.—Robert J. Grant, superintendent of the U. S. Mint, has been instructed from Washington to reduce the number of employees from 240 to 120 men. Two of the three shifts now employed coining silver at the rate of 225,000 dollars daily will be laid-off.

which is a 130-ft. drift. A greater number of the stockholders are residents of Kellogg and employees of the Bunker Hill & Sullivan company.

Pend Oreille.—The Clarinda Mining Co. has awarded a contract for the completion of tunnel No. 5 to the Lone Pine vein. The tunnel has been driven 1190 ft. and should cut the vein within the next 25 ft. Stringers, carrying chalcopyrite, have been cut in driving this tunnel.

MICHIGAN

Houghton.—The shipment, lake and rail, of 51,000,000 lb. of copper out of the Lake district between April 1, the date of the shut-down of the Calumet & Hecla and subsidiary mines, and November 1, compares with an estimated production during that period of 45,000,000 lb. This takes into consideration Copper Range, Quincy, Mohawk, Wolverine, and Calumet & Hecla refinery production. When the C. & H. mines closed, the parent companies and subsidiaries had on hand approximately 90,000,000 lb. of unsold copper. The other companies had comparatively small stocks. While Calumet & Hecla has reduced its metal surplus considerably, there still is an abundance of copper in the district, which accounts largely for the fact that there will be no resumption of operations by the Calumet & Hecla mines this winter. A production of 45,000,000 lb. during seven months is small

In comparison with the normal output for the district, which is in excess of 22,000,000 lb. per month.

The Quincy Mining Co. has opened a logging camp in a timber tract it owns near Hancock, which will give employment to a small crew of men until March 1.

The Copper Range mines are gradually building up their forces, making a net gain of 50 men in September and 40 in October. October production showed a small increase but not in proportion to the number of new men taken on. This is accounted for by the fact that it usually takes a little time to get stopes ready and prepare working places. With the gradual increase of forces, however, the Copper Range mines should show some gain in production each month from this time on.

At Ahmeek, extensive repairs are under way in No. 2 shaft, where the concrete skipway, which has crumbled in places, is being replaced with timber. It will require several months to complete this work.

A rather extensive program of drifting and stoping is under way in all four Mohawk shafts with the ore averaging 23 lb. per ton. Mohawk is using both level- and drift-scrappers with a large measure of success, the devices being particularly effective in the levels, where the cost of handling has been reduced almost 50%.

Bruce A. Middlemiss, a graduate of the Michigan College of Mines, is said to have worked out a process for the hardening of copper. He recently returned from Chile, where he represented the Guggenheim interests and where he conducted his experiments. With copper he uses 3% alloy. The product is declared to be ideal for automobile gears and similar parts. A patent covering the process, which is secret, is now pending. Tests have been made to show the hardness and toughness of the product and it is said several of the leading automobile manufacturers are interested and ready to place orders. Gears made of this copper are capable of withstanding great wear, it is claimed, and will not chip or break. Mr. Middlemiss has interested sufficient capital to build a factory for the manufacture of gears.

While a reduction of 25% in the freight-rate on copper bullion, ores, and concentrates, has been announced, this will have little effect here. There will be no reduction in the freight-rate on refined copper; beginning December 1, marking the end of the season of navigation, the all-rail rate will be 76c. per 100 lb., plus 3% war-tax, which will bring it up to better than 78c. The combined lake and rail rate is 49c., so a considerable saving is made on all copper shipped during the season of navigation. The metal can be stored in the East for as low as one cent per 100 lb. High freight-rates are still a large factor in mining costs. The price of steel and powder is still far in excess of the pre-war figure, but the difference is largely due to the freight-rates. Drill-steel has dropped slightly in price, now being 17c. per pound, while powder also has taken another drop, the present price being \$15.05 per case, compared with \$15.55 in September. Forest products have advanced 10% in price in the last 30 days.

MINNESOTA

Minneapolis.—Plans are completed for the construction of the new building of the Mines Experiment Station of the University of Minnesota. This plant will cost approximately \$250,000 and is expected to be the most complete and well equipped ore-testing laboratory ever built. E. W. Davis is superintendent of the Station.

MONTANA

Butte.—The East Butte Copper Co. is producing around 1,500,000 lb. of copper per month and is earning a profit on its own operations outside of the treatment of Davis-Daly ores. Ore at the mill is averaging about 80 lb. copper per ton and the tailing from 2 to 3 lb. of metal. Blister cop-

per is averaging 75 oz. silver per ton. Although East Butte orebodies are narrow, some of the cleanest mining in the district is being done, and when the new shaft is completed, about the first of the year, still greater efficiency is looked for, as on the deepest level of the Pittsmont property, the 1800-ft., ventilation is not good. The new shaft will permit the establishment of a direct current of air by means of raising and sinking. Gold extraction at the Elkhorn mill of East Butte is expected to be under way in a day or two as all the tanks have been filled with cyanide solution and crews have left Butte for the Elkhorn prop-

North-Eastern Washington

erty. With cyanide somewhat cheaper than during the height of the War, it is believed East Butte will be able to make a profit on treating this ore.

NEVADA

Candelaria.—Work will commence within two weeks on the construction by the Candelaria Consolidated Mines Co. of a 300-ton mill at a cost of \$200,000. C. D. Kaeding is general manager for the Candelaria company, while the Western Oil Purchasing Co. and the Rochester Silver Corporation are involved in the financing of the new plant. Candelaria is one of Nevada's famous old camps from which some \$30,000,000 in dividends was paid prior to 1875.

Mina.—Everything is in readiness to try out the new mill of the Simon Silver-Lead Co. Representatives of the Minerals Separation company and metallurgists from the U. S. Bureau of Mines will be present at the initial run. A selective flotation of zinc and lead will be made, and the operation, accordingly, is of particular interest. Lawrence F. Barber has been engaged to take charge of the flotation work. The mill is connected with the mine by a rail tramway, over which ore will be transported by mule-trains.

This tram connects with the shaft at a depth of 30 ft. from the surface by means of a short tunnel. An ore-pocket of 250 tons capacity extends from the tunnel to the surface. Ore for the mill will be hoisted to the top and dumped into the pocket and loaded into cars by means of automatic gates. In the mine, ore-pockets of 100 and 200 tons capacity, respectively, have been provided.

Oscosola.—Baird & Tilford Bros. has shipped another bar of gold bullion resulting from the milling of a small lot of \$80 to \$90 ore. The ore comes from an adit that has followed the vein for 240 ft.—The Marriott mill is also in operation on ore averaging \$40 per ton in gold.

Ploche.—Since the completion of the repairs of the Bristol Silver Mines tramway 50 tons of Bristol ore have been carried over the mountain daily and, with the Black Metals mine also sending out a car per day, the outlook is good for the coming winter. The mines contributed to the tonnage

groups.—The Sylvanite group two miles above Gold Hill on Rogue river, which was recently acquired by the Oregon-Pittsburgh Mining Co., is in charge of L. H. Van Horn. Plans for a 100-ton mill, a power-plant on the Rogue river, and heavier mine-equipment are being made. Material is being assembled to erect a large number of cottages and quarters for the employees at the mine.

The Manganese Ore Mining Co., of Terra Haute, Indiana, has just spent \$100,000 in erecting a modern electrically driven dredge of the drag type. The company has laid a 3-in. pipe-line from Rogue river at Gold Hill, which is to deliver water pumped to the plant.

UTAH

Alta.—The ore-shoot recently opened at the Alta Tunnel & Transportation Co.'s property continues to improve, according to Herman Johnson, superintendent. The fourth lot averaged 46 oz. in silver and 40% lead, which is higher than

Ore-Car Used at the Britannia Mine, Howe Sound, B. C.

shipped during the week ended November 12 in the following amounts: Black Metals, 365 tons; Bristol Silver mines, 225; Hamburg lease, 50; total, 640 tons.

Tonopah.—Two five-ton trucks arrived from Royston on November 8 with the first shipment of 10 tons of high-grade taken from the Betts lease on the Hudson estate, where the original discovery was made six weeks ago. The ore will be treated at the MacNamara mill, as it is the desire of W. H. Royston, manager for the Hudson company, to save the producers the transportation charge of \$90 per ton to haul the ore by express to the Coast. The value of the ore is variously estimated but the silver minerals can readily be seen with the naked eye.

OREGON

Gold Hill.—The Millionaire and Gold Ridge groups, both three miles south from Gold Hill, are producing, each with 10-stamp mills. Other mines within a radius of five miles from Gold Hill, which are being re-opened and re-equipped, that will soon be producing, are the Sylvanite, Red Oak, Blossom, Lucky Bart, Roaring Ginlet, Corporal G, Braden, Bill Nye, Kubli, Nellie Wright, Alice, and Gold Hill Pocket

the average of previous shipments. The ore averages 6 ft. in width at present.

Big Cottonwood Canyon.—The Big Cottonwood Coalition Mines Co. has purchased the compressor, transformers, etc., of the Iowa Copper Co. The company has also built about 400 ft. of snowsheds and purchased additional mine-cars. C. E. Robertson, secretary-treasurer, states that development will be hastened during the coming winter.

Enreka.—High-grade ore has been entered in a winze 50 ft. below the tunnel level at the Butcher Boy mine in South Tintic, by Davis and Presby, lessees. This property was formerly known as the Showers Consolidated, and is controlled by the R. J. and M. H. Walker estates of Salt Lake City. Eighty tons of ore, averaging 150 oz. silver, has been shipped, and a second shipment will be made shortly. —Ore shipments for the week ending November 5 totaled 191 carloads, as compared with 168 cars for the preceding week. The Tintic Standard shipped 81 cars; Chief Consolidated, 39; Dragon, 15; Victoria, 15; Eagle & Blue Bell, 12; Iron Blossom, 11; Colorado, 6; Swansea, 7; Empire, 3; Gemini, 1; Sunbeam, 1.

Two new furnaces are being installed at the Tintic Standard Mining Co.'s mill. This will make a total of nine furnaces, with a total capacity of 200 tons of ore per day. It is believed the furnaces will be ready for operation December 1. E. J. Raddatz, president of the company, reports operating conditions at the mine and mill as satisfactory.

Milford.—The face of the adit-level being driven at the Galena Mining Co.'s property is now in a distance of 310 ft., according to Frank L. Osborn, who is in charge of the work. The Galena mine was a shipper of high-grade ore in the early days, but has been idle for some years.

Moab.—James S. James, superintendent of mines for the Radium Company, of Denver, announces that the recent curtailment of operations by his company in the Gateway district was caused primarily by the inactivity in the radium and vanadium markets. During the period of curtailment, the company will continue development work at its four mines, and also make needed improvements in the plants at Denver and Boulder.

M. I. Fowler reports that ore has been found in the Tornado group of claims, 18 miles east of here, at the north end of the La Sal mountain range. Work on the Tornado vein, at its intersection with an iron fissure, has resulted in opening ore assaying from \$8 to \$10 in free-milling gold, while some samples show as high as \$200 per ton in gold. A copper-gold vein, 28 ft. wide, assays from \$6 to \$75 in gold, and from 6% to 25% in copper. A tunnel is being driven to connect the various workings of the Tornado group.—At the Panama Mining Co.'s property, 2 miles east of the Tornado group, development is being continued on the high-grade silver-copper deposit opened up some months ago, according to Fred McCoy, who is in charge of the work.

Park City.—Ore shipments for the week ending November 5 totaled 1979 tons, of which the Judge allied companies shipped 933; Silver King Coalition, 568; Ontario, 428; and the New Quincy, 50. Shipments the previous week totaled 2140 tons.

The second shipment from the new orebody at the New Quincy property totaled 39 dry tons and assayed 76.2 oz. silver, 19.2% lead, 16.3% zinc, and 37.2% insoluble, netting the company about \$66 per ton. This is richer than the first shipment.

Salt Lake City.—An organization known as the Metals Extraction & Refining Co. has been formed by Salt Lake City and Ogden men to promote the Croner process for treating black sands. C. B. Croner, a Los Angeles mining engineer, is president. He states that his process has been demonstrated a success in recovering gold and platinum in placer mining, particularly in cases where the metals are in too fine a condition to be recovered by methods heretofore employed. Mr. Croner states that one plant is now in operation on the Snake river in Idaho, where his process is being used with satisfactory results, and that recently tests have been made in the experimental plant at Ogden on tailings. The process combines chemical and mechanical treatment.

WASHINGTON

Cotville.—Operations have been resumed at the Old Dominion mine. A drift has followed silver ore for 14 ft. At the place of discovery the ore had a width of nearly 3 ft. and a metallic content that averaged \$1140 per ton. This was at a depth of more than 700 ft. on the dip of the vein, and at a point 2200 ft. from the portal of the tunnel. Work was discontinued last September to permit the installation of ventilating equipment. This has been completed. W. H. Linney is general manager for the Dominion Silver-Lead Co.

WISCONSIN

Shullsburg.—The M. & P. Mining Co., operating the Pacquette mine, has made its first sale for the season to

the American Metal Co. The ore is high grade. The Pacquette mine is fully equipped and a shaft is bottomed in ore. Production will now be steady under contract agreement.—The Rodhams Mining Co. has a force of men at work opening a new vein of lead ore recently discovered. The ore will be trammed overhead to the Rodhams mill. Sales were made during the month of lead ore amounting to several hundred tons, this going to the Federal Lead Co.

Day Siding.—The Vinegar Hill Zinc Co. is operating the North Unity mine with good results. Daily shipments of zinc ore are made to the National Separators. Sales of lead ore have been made to the Federal Lead Co. New ground is being drilled for the Vinegar Hill interests.

Galena.—The Burr Mining Co. has a small force of men at work under the charge of Watt Nolen, superintendent. New ground is being proved and the mill and mine equipment is being overhauled and put in shape to resume operation.

BRITISH COLUMBIA

Cranbrook.—Lynch Brothers, of Seattle, have been awarded a contract to explore the properties recently acquired by the Federal Mining & Smelting near Kimberley with a diamond-drill. A rig has been set up on the Federal claim, and Dan Lynch is superintending the work.

Hope.—The Liberator Mining Co. has purchased the stamp-mill and other machinery at the Lemon mine, near McKinney camp, and is transferring it to the Emancipation mine.

Nelson.—B. Cortiana has started a second tunnel at the Rampulo group, in the Lightning Peak district, which will give a depth of another 100 ft. on the vein. Cortiana has developed a good body of silver-lead ore at the surface and in the 400-ft. tunnel.—Andrew Johnston has packed 20 tons of ore from his property at Woodbury creek, in the Ainsworth district, to Kootenay lake, and shipped it to Trail. The last shipments from this property gave a return of close to \$1000 per ton in silver and lead, but, owing to the depreciation in prices of metals the present shipment is not expected to bring much over \$600 per ton.—The Railway Commission has reserved judgment in the application of the Great Northern Railroad Co. to abandon its Red Mountain branch and take up the rails, and suggests that it should come to an amicable agreement with the C. P. R. to take over the Rossland spur. The petition was opposed by the city of Rossland and by the Le Roi No. 2 Mining Co. C. R. Hamilton, attorney for the latter, stated that the mine represented an investment of \$3,000,000, and would have to be closed if the railway were abandoned. E. H. McNeill, representing the railway company, offered to sell the spur connecting the mine with the C. P. R. for \$3000, or give it to the mining company, at the option of the commission. It appears, however, that the line is too lightly constructed to carry C. P. R. engines.

Stewart.—John Hovland is shipping from his mine on Fish creek and Skookum creek. He expects to have about 20 tons of high-grade ore ready for shipping by the time the roads are in condition to transport the ore.—Clay Porter and George Mehlfield have been developing an 18-in. vein of galena, rich in silver, at the Idaho group, at the north fork of the Marmot river; they will ship between 20 and 30 tons during the winter. The ore has to be hauled to the fork of the river.

Vancouver.—The Dominion Government assay-office gold receipts for the first ten months of the year totaled \$2,569,976, compared with \$1,808,970 for the corresponding period of last year. Though this included the production of the Yukon, as well as British Columbia, nearly half the gold output of British Columbia is refined in the United States, and consequently does not pass through this office. The-

receipts indicate that the gold production of the Province will show an increase of about 40% over that of last year.

MEXICO

Chihuahua.—John L. Ostrom has taken over the Cerra de Plata group of mines, situated in the municipality of Zaragoza. The property comprises 18 contiguous claims which produce silver, copper, and lead ores.——J. F. Carter, of Jimenez, has associated himself with Federico F. Nunez in La Doncella mines in the Boaz mountains of the Allende mining district, adjoining the Amargoza properties.——Adam S. Schaefer, of Parral, has added a number of new prospects to his holdings in the Parral district. Last week he filed with the mining agent application for titles to Las Recompensa group of six adjoining claims near El Nacimiento and Refugio mines in the municipality of Zaragoza. Schaefer has several other properties in this region which he is developing.——Francisco Villegas has also recently recorded a new group of mines known as the San Carlos with the Parral mining agency. They are situated in the rich Santa Barbara district.——Henry Muller, of Chihuahua City, has made some locations in the Santa Eulalia camp.

A general meeting of the stockholders of the Ahumada Mining Co. has been called to meet at the offices of the company in Juarez on December 5.——The Carmelita and Laura Mining companies will hold a joint meeting of shareholders in the City of Chihuahua on November 24 for the purpose of electing new officers and hearing the reports of the boards of directors.

ONTARIO

Howry Creek.—At the Bosquet gold mine situated in this district, 60 miles south-west of Sudbury, a vein from 2 to 6 ft. wide has been opened up for 2000 feet.

Larder Lake.—There is much activity in this district following the satisfactory results of the development of the Costello vein by the Crown Reserve and Canadian Associated Goldfields. The vein is 15 to 60 ft. wide and has a known length of one mile of which over half is on the Associated Goldfields property. The ore is of medium grade. Hundreds of claims have been staked in the vicinity. The Coniagas, of Cobalt, has secured 300 acres and a campaign of exploration has been undertaken. Practically the entire district between Larder Lake and Kirkland Lake, 25 miles distant, is now staked over a width of about five miles and prospectors are now looking for small patches that may have been overlooked.

Porcupine.—J. H. Black, manager for the Northern Canada Power Co., states that there is now enough water in storage to supply the Porcupine mines with power until the end of March. He intimates that negotiations are under way looking to a provision for the future needs of the camp.

The orebody found on the 7th level of the Dome Mines has been proved to be large. Diamond-drilling has indicated a depth of at least 150 ft., but owing to its irregular shape and uncertainty as to its dip it will need further development. A drift toward it is being run on the 8th level.

The new shaft planned by the Hollinger Consolidated will probably be started on the south side of the property comparatively near the boundary of the Vipond-North Thompson. A fact of material importance to the latter company is that the greenstone-schist formation in which the largest of the Hollinger orebodies occur is found to be dipping sharply south toward the V. N. T. property.

West Shining Tree.—The Kingston property consisting of three locations half a mile east of the White Rock has been purchased outright by an English syndicate for a sum stated at upward of \$150,000.——Arrangements have been made for the re-opening of the Atlas, capital having been secured for the sinking of a shaft to a depth of 300 ft. and extensive lateral development. A force of men is being engaged.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Glenn L. Allen is at Guadalupe, Zacatecas, Mexico.

F. M. Dancy has moved from New Orleans to New York.

Clarence E. Melssner has moved from Zacatecas to Mexico City.

F. S. Rawson has returned to San Diego, California, from Mexico.

William T. Macdonald is in southern California for about a week.

Cyril Williams, Jr., has moved his office to 369 Pine street, San Francisco.

F. G. Cottrell has been elected an honorary member of the Société de Chimie Industrielle.

Owen Letcher is on a tour through India, but expects to return shortly to Johannesburg.

C. W. Purington sailed on November 18 from Vancouver on the 'Tyndarius' for Yokohama.

H. B. Hart has been appointed research chemist for the Eagle-Picher Lead Co., of Joplin, Missouri.

F. H. Hamilton, who has been on a visit to Porcupine, sailed from New York on October 25 for London.

S. M. Soupcoff, mining engineer for the American Smelting & Refining Co., has returned to Salt Lake City from Colorado.

George W. Lambourne, president of the Judge allied companies at Park City, Utah, has returned to Salt Lake City from Chicago.

Edward R. Weidlein, of the University of Pittsburgh, has been appointed a director of the Mellon Institute of Industrial Research.

Edwin E. Chase and his son R. L. Chase, of Denver, have been in the Katherine district in Arizona, and have gone to Tucson on mine-examination work.

C. M. Gay and Norman H. Gay have reorganized their firm, which is now called the Gay Engineering Corporation, with offices at Los Angeles, as formerly.

F. C. Henriques, recently at the Bureau of Mines station at Berkeley, is now chief chemist for the Sampson Magnesite Co., Inc., at Sampson Peak, Mendota, California.

Henry T. Neal, manager in San Francisco of the purchasing department of the Metals Exploration Co., was married on November 16 to Miss Laura M. Miller.

George M. Douglas has returned to the Cananea Consolidated Copper Co., at Cananea, Sonora, Mexico, after having spent a year at Lakefield, Ontario, Canada.

T. H. O'Brien, general manager of the Inspiration mine, P. G. Beckett, assistant to the president of the Phelps Dodge Corporation, and C. La Grande have returned from Europe.

D. C. Jackling left San Francisco on November 9 for a trip of inspection to the Nevada Consolidated, Utah Copper, Chino Copper, and Ray Consolidated properties. He will return in about three weeks.

Charles T. Arkins, mining engineer, who some years ago was in charge of the Golden Horseshoe mill at Kalgoorlie, in Western Australia, and then went to London, where he acted as consulting engineer for the Broken Hill Proprietary Co. in the first lawsuit over the oil-flotation process, died at Los Angeles on October 21. He was for a number of years connected with the Allis-Chalmers Mfg. Co. and Fairbanks, Morse & Co., and while with them traveled extensively in Alaska and British Columbia. While in the latter country he acted in an advisory capacity on the feasibility of exploiting the goldbearing alluvium of the Yukon valley.

Zinc dust, cents per pound.....	9.00—9.50

EASTERN METAL MARKET

(By wire from New York)

November 14.—Copper is active and strong. Lead is quiet and firm. Zinc is dull but steady.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46.05 pence per ounce (025 fine), calculated at the normal rate of exchange.

Date	New York cents	London pence	Average week ending Cents	Pence

THE SILVER MARKET

The following is quoted from the latest market letter of Samuel Montagu & Co., of London:

During the week movements of a somewhat sharp description have been recorded. On October 24 prices fell $\frac{1}{4}$ d., and on the 25th a further penny, to $39\frac{1}{4}$ d. for cash and $38\frac{1}{4}$ d. for two months delivery, the lowest prices recorded for six weeks. Yesterday they both recovered a halfpenny, and today a further $\frac{1}{4}$ d. and $\frac{1}{2}$ d. for cash and forward delivery, respectively.

Many would be glad to know the reason for these changes, which are not heralded by any warning. To gain it, we must look below the surface, and reach the speculative forces which sway silver and many other commodities, as well as the foreign exchanges. For some time past no stable ground has been under our feet in the world condition of affairs. On the whole, some slight amelioration is taking place, but currency inflation, exaggerated prices for goods, and the legacy of unrest left by the War, afford great room for snatching profits—and also incurring losses—by gambling in any counters that are ready to hand. Among other commodities, silver has been selected for the purpose, and the fact that it governs, or is governed by the Far Eastern exchanges, renders it specially suitable; for it can be dealt in as a counterpoise to operations in the China exchange. Hence, given large unexpected sales or purchases upon a rather indifferent silver market, quick falls and rises in the price are only to be expected. Forecasts as to prices in the near future are therefore futile in the circumstances to which we have alluded.

India seems for the time being to have ceased acquiring the metal, and competition between her and China is therefore absent, but there appear to be two classes connected with China holding diverse views, and not infrequently they operate here either on the same day or some days not far apart. To them is principally owing the irresolution of the market. At the same time silver is being actually shipped to China.

We learn from a mail correspondent in Bombay that there was expected to be a good demand for silver after the holidays, provided the price was not too high, and that inquiry was disposed to languish when the quotation neared Rs 100. As a matter of fact, the feeling in the Bazaars now seems to be bearish. The recent setback in the sterling value of the rupee, as well as their uneasiness about silver, are possibly not unconnected with a falling off in the Indian balance of trade, which is given officially as plus Rs 1300 for September, as against plus Rs 234 for August. As regards exchange, however, the relation cannot be very intimate, for exchange is often fixed for months ahead, and not from day to day.

The Customs report of Yunnan, China, for 1920 throws interesting light upon the local conditions of currency. It states that the scarcity of silver caused prohibition of export of silver coins in 1919, and the prohibition was strictly maintained during 1920. Gold \$10 pieces appeared in October 1919, and a \$5 gold coin was put in circulation at the beginning of the year. Both these coins were in common use until the end of the year, when, the sudden fall in silver having increased their value, they soon disappeared from circulation.

MONEY AND EXCHANGE

Foreign quotations on November 15 are as follows:

Sterling, dollars: Cable	3.97 $\frac{1}{2}$
" Demand	3.97
Franc, cents: Cable	7.30
" Demand	7.28
Lira, cents: Demand	4.19
Mark, cents: Demand	0.40

Eastern Metal Market

New York, November 9.

An optimistic tone pervades most of the markets and demand in most cases is fair.

Inquiries for copper are broadening and sales are satisfactory at firm prices.

The tin market is inactive, but prices are firm.

Quietness and steadiness rule in the lead market.

A spurt in values has been the feature of the zinc market.

Antimony is inactive and nominally unchanged.

Yesterday, Tuesday, was a holiday due to election.

IRON AND STEEL

Steel production in October was 1,616,810 tons of ingots by the 30 companies reporting, or more than double the 803,376 tons reported by the same companies in July. The increase in October over the September steel output was 37%, whereas pig-iron output in October was but 22% more than in September. The Steel Corporation's schedule this week represents 51% of capacity.

Railroad inquiry for rails for 1922, and what may be the beginning of better buying of cars, have appeared during the past week. Otherwise the chief developments in the steel market have been the letting of tin-plate contracts for the first half of next year and some good business in wrought pipe. Rail inquiries for next year include 100,000 tons for the New York Central, with a possible 200,000 tons, also 40,000 tons for the Norfolk & Western. The Pennsylvania Railroad is considering a 1922 quota of 150,000 tons. Thus far the leading interest has booked 120,000 tons of rails since the \$40 price was named. Orders for 2500 cars for the St. Paul represent 29,000 tons of steel.

Though the upward turn in production came in July, further price deflation on the present movement is recorded for this week. 'The Iron Age' composite for finished steel now stands at 2 13/4c. per pound, or less than 27% above the average for ten years before the War.

COPPER

While prices as judged by the minimum price have not advanced, the market is much more active and firmer at 12.75c., refinery, or 13c., delivered, for electrolytic copper. A few sellers are offering at this level but there are other large producers who either quote at least 1/4c. higher or are not quoting at all. Buying for both domestic and foreign account is distinctly better and inquiry is more voluminous. A feature of the latter is the interest in 1922 delivery. One company is reported to have purchased its 1922 supply, paying cash for it this year. Others are interested in first-quarter delivery. Significant is the estimate that sales for October amounted to 140,000,000 lb., while output of refined copper is not more than 40,000,000 lb. per month. Deliveries into consumption in October are not yet estimated, but up to that month they had averaged about 70,000,000 to 80,000,000 lb. per month.

TIN

A leading importer characterizes the market for Straits tin as almost stagnant. There was a little business in January-February shipment on November 3, but spot demand has fallen off. What inquiry there is centres in far-off positions rather to the neglect of the intermediate. Firmness in the pound sterling has been the sustaining factor so that the price of spot Straits, New York, has been firm to higher, the quotation on Monday standing at 28.62 1/2c., New York, yesterday having been a holiday, due to the 'Tammany landslide'. The London market has been higher with quotations on Monday at £158 10s. for spot standard, £160 for future standard, and £159 per ton for spot Straits. Arrivals thus

far this month have been 505 tons with 4450 tons reported afloat.

LEAD

Demand is steady at unchanged price-levels. Electrical, pigment, and cable interests are the most active buyers. Inquiries for future consumption are also good. Outside producers maintain their quotations at 4.40c., St. Louis, or 4.70 to 4.75c., New York, while the leading interest continues to quote 4.70c., New York and St. Louis.

ZINC

A rather unusual situation has been the feature of the market the past week. Unexpected buying by one or two interests, acting as dealers or buying to fill contracts, has caused a decided advance in quotations. Consumers have been only lightly interested. As a result of this demand from special sources prime Western for November or early delivery is now quoted at 4.75c., St. Louis, or 5.25c., New York, as a minimum, with but little available. Producers sold quite liberally into the November output and are not anxious for a large volume of business now.

ANTIMONY

The market is quiet and without feature with wholesale lots for early delivery quoted at 4.75c., New York, duty paid.

ALUMINUM

Wholesale lots of virgin metal, 98 to 99% pure, are quoted by the leading producer at 24.50c. per pound, f.o.b. plant, but this is probably being shaded because the same grade from importers is available at 17 to 18c., New York, duty paid.

ORES

Tungsten: Stagnation rules and quotations are nominal at \$2.50 per unit up, depending on the grade, delivery, etc.

Molybdenum: There are no features or demand with quotations nominal at 50c. per pound of MoS₂ in regular concentrates.

Manganese: The market is devoid of inquiry or interest with quotations nominal at 20c. per unit, Atlantic seaboard, for high-grade foreign ore.

Chrome: There seems to be no demand or interest with nominal quotations unchanged at \$20 to \$26 per net ton, c.i.f. Atlantic seaboard, for foreign ores, standard quality, depending on analysis, etc.

FERRO-ALLOYS

Ferro-manganese: The most interesting development is that the U. S. Steel Corporation has been a seller recently. While inquiry is light with only three 50-ton lots noted, the domestic alloy can be bought at \$60, Pittsburgh, against a quotation of \$58.35, seaboard, for the British. There are indications that domestic producers intend to make prices so as to hold their full share of the trade.

Spiegeleisen: The market is inactive with quotations unchanged at \$25 to \$26, furnace, for the 20% alloy.

Ferro-tungsten: No business is heard of with quotations nominal at 40 to 45c. per pound of contained tungsten in the case of the domestic alloy with the foreign quoted at 50c., duty paid, seaboard.

Ferro-silicon: A more active inquiry is reported amounting to 150 tons in the aggregate. A large Michigan consumer has bought 100 tons or one month's supply. Prices range from \$55 to \$60 per ton, delivered, depending on the seller.

Ferro-chromium: Regular standard alloy is quoted by one large producer at 14c. per pound of contained chromium, delivered, but there are indications that it can be bought under some conditions as low as 10 to 11 cents.

Company Reports

INTERNATIONAL NICKEL COMPANY

Report for the quarter ended June 30, 1921.

Financial: Earnings, \$390,198.54; other income, \$119,003.69; net income, \$372,122.17; profits, \$179,402.03; dividends, \$133,689.

RAY CONSOLIDATED COPPER COMPANY

Report for the quarter ended June 30, 1921.

Financial: Operating loss, \$85,619.35; plant shut-down expense, \$289,994.04; miscellaneous income, \$5403.87; net loss, \$370,209.52.

Production: Copper contained in concentrate, 1,605,654 lb.; net production of copper, 1,546,535 pounds.

Remarks: Issuance of quarterly reports will be discontinued until operations are resumed.

MOUNT MORGAN GOLD MINING COMPANY, LIMITED

Report for the year ended May 29, 1921.

Property: Mines and plants in Queensland, Australia.

Financial: Total revenue, £1,038,682 18s. 2d; balance forward, £212,350 7s. 8d.

Production: 167,802 tons was treated in the concentrator for the production of 60,033 tons of concentrate. The smelter produced 5147 tons of copper and 76,463 oz. gold.

Reserves: 3,527,287 tons containing 2.57% copper and 6.04 dwt. gold.

SHATTUCK ARIZONA COPPER COMPANY

Report for the quarter ended June 30, 1921.

Financial: Development expense, \$90,264.02; total expense, \$94,926.72; net development returns and interest, \$30,874.36; net expense for quarter, \$64,052.36.

Development: 3265 ft. A new and important discovery of copper ore was made and is now being developed on the 600-ft. level near the boundary of the Roy and Leo mining claims in the north-east end of the property.

Production: Copper recovered, 152,578 lb., silver, 5397 oz.; gold, 22.34 ounces.

RENGUET CONSOLIDATED MINING COMPANY

Report for half-year ended June 30, 1921.

Financial: Receipts, \$598,217.42; expenditures, \$238,785.57; gross profit, \$359,431.85; net profit, \$283,984.15; capital distributions of five centavos each per share were made on March 31 and June 30, totaling \$100,000.

Production: 18,904 tons of ore was treated for a return of bullion valued at \$586,139.98.

Remarks: Development has been satisfactory; the item of propable ore in the last report now becomes positive ore, and a large portion of the possible ore becomes probable ore.

NEW MODDERFONTEIN GOLD MINING CO., LTD.

Report for the quarter ended June 30, 1921.

Property: Mines and plant at Johannesburg, Transvaal, South Africa.

Operating Official: E. M. Sharp, manager.

Development: 12,995 ft.; ore-reserves, 8,884,600 tons containing 8.4 dwt. per ton.

Production: 236 stamps and 14 tube-mills crushed 1,083,000 tons containing 9.96 dwt.; 6.424 dwt. per ton was recovered by amalgamation, and 3.317 dwt. per ton by cyanidation; residue contained 0.293 dwt.; theoretical as well as actual extraction by amalgamation was 64.5%; theoretical extraction by cyanidation was 32.7%; actual, 33.3%. Total actual extraction of gold amounted to 97.8%.

Financial: Total revenue, £2,969,198 2s.5d.; total work-

ing costs, £1,270,146 3s.4d.; working profit, £1,699,051 19s.1d.; dividends, £1,400,000; dividends to date, £7,433,750.

UTAH COPPER COMPANY

Report for the quarter ended June 30, 1921.

Financial: Net loss from copper production, \$42,022.20; plant shut-down expense, \$547,583.68; miscellaneous income, \$145,367.21; loss, \$444,229.67; distribution to stockholders, \$812.245; deficit, \$1,256,474.67.

Production: Copper contained in concentrate produced, 1,406,085 lb.; net production of marketable copper, 1,480,697 pounds.

Remarks: The issuance of quarterly reports will be discontinued during the remainder of the period of temporary suspension of operations.

CHILE COPPER COMPANY

Report for the quarter ended June 30, 1921.

Financial: Total income, \$423,378.08; total charges, \$1,533,411.46; loss, \$1,110,033.38.

Production: Copper output, 12,001,873 lb.; ore treated, 335,871 tons of ore, averaging 1.75% copper.

Remarks: The above-mentioned loss of \$1,110,033.38 includes the sum of \$697,249.54 for depreciation, which is a book entry and is computed on a time basis, regardless of production or sale. The company had on hand on September 1, \$8,813,000, representing cash and marketable securities, after setting aside \$1,921,000 to complete the payment of purchase price of two tank-ships mentioned in the annual report.

KERR LAKE MINES, LTD.

Report for the year ended August 31, 1921.

Property: Mines at Cobalt, Ontario, Canada.

Operating Official: H. A. Kee, mine manager.

Financial: Expenses, \$145,555.46; receipts, \$195,820.26; dividends paid, \$300,000; balance to balance-sheet, \$178,979.51.

Development: 3341 feet.

Production: Shipments during the year amounted to 282,075 oz. silver.

Remarks: During the early part of 1921 an opportunity presented itself to acquire the Hargrave property adjoining the Kerr Lake mine. The ore taken from this mine has already returned the purchase price.

GREENE CANANEA COPPER COMPANY

Report for the year ended December 31, 1920.

Property: Mines and works in Chihuahua, Mexico.

Operating Official: T. Evans, general superintendent.

Financial: Gross income, \$7,299,918.84; net income, \$560,078.50; dividends, \$500,000.

Development: 76,431 feet.

Production: The concentrator treated 288,176 tons of ore and produced 82,572 tons of concentrate; the smelter treated 782,989 tons of ore and concentrate; the yield amounted to 43,672,939 lb. copper, 1,778,617 oz. silver, and 10,089 oz. gold.

General: It was decided to join with the majority of copper producing companies in Arizona in subscribing to the capital stock of the Apache Powder Company. This plant is near Benson, Arizona, and is nearing completion.

AMERICAN SMELTING & REFINING CO.

Report for the half-year ended June 30, 1921.

Financial: Net earnings, before deducting administrative expenses and corporate taxes, \$2,448,566.16; net income from current operations, before providing for bond interest, depreciation, obsolescence, and depletion, and after provid-

ing for all taxes, \$1,919,015.51; balance after deducting depreciation and depletion, \$1,001,837.71; balance before deducting dividends, loss, \$1,101,831.49; net loss for period, \$3,203,966.74; total profit and loss surplus, \$22,783,325.91; dividends, \$2,102,135.25.

Remarks: The dividend on the preferred stock is cumulative; the conservative policy of the management in the past having built up during more prosperous times a large surplus for such periods as the one the company is now passing through, the directors have felt justified in continuing the payment of the preferred dividend. All the properties of the company are in excellent condition; a slight improvement in general economic conditions is perceptible.

TEMISKAMING MINING COMPANY, LIMITED

Report for 18 months ended June 30, 1921.

Property: Mines and mill at Cobalt, Ontario, Canada.

Operating Official: G. F. Dickson, general manager.

Financial: Production, \$179,294.67; administrative and general expenses, \$366,539.47; deficit, transferred to surplus, \$135,765.50.

Development: 1316 feet.

Production: 34,911 tons was milled for a total production of 243,029.2 oz. of silver.

Remarks: At the time that the mine was closed down through shortage of power in November last the price of silver was 70c. per ounce, which was sufficient to leave a margin of profit. The further fall since that date to about 60c. per ounce would be barely sufficient, even with the increased extraction from the tailing plant, to permit the continuance of exploration and development work. The mine, therefore, remains closed. The likelihood of discovering any appreciable quantity of high-grade ore in the old workings is small, but there is scope for developing a considerable tonnage of medium-grade ore that, under the improved conditions of working, would show a reasonably good profit with silver at 70c. per ounce.

ARIZONA COPPER COMPANY, LIMITED

Report for the nine months ended May 31, 1921.

Property: Mines, mill, and smelter at Clifton, Arizona.

Operating Official: N. Carmichael, general manager.

Financial: From copper production, £378,973 3s.11d.; working expenses, £543,320 15s.; net deficiency at May 31, £244,123 17s.2d.

Production: Ore treated at concentrators, 549,071 tons; ore smelted, 80,710 tons; copper produced, 18,550,000 pounds.

General: An arrangement has been made whereby the undertaking is sold to the Phelps Dodge Corporation, excepting the Edinburgh office, a sum of about £35,000, and the right to certain British tax recoveries. The price is: payment of the dividends on the 'A' preference shares and preference stock, and retirement of these shares and stock within five years; 50,000 fully-paid shares of \$100 each of the Corporation, of which the capital will then be 500,000 shares of \$100 each; the purchaser assumes all the liabilities, other than undisclosed contingent liabilities, not incurred in the ordinary course of business. The company is to have the right to nominate a director of the corporation.

UNITED VERDE MINING CO.

Interim report dated November 1.

The smelting works have remained closed, and in the mine only a small force of men has been employed on necessary work. Development work has been restricted, and no additional ore-reserves worthy of mention have been uncovered. Copper sales, at about 12c. per pound during the six months period in review, have reduced the metal in

hand to 9,976,000 lb. In order to sell refined copper at present prices at New York, before production is resumed there must be a material reduction in freight-rates, not only on the metal produced, but on all commodities entering into its manufacture. It is hoped that such reductions may be secured in the near future. Arizona State taxes at present are prohibitive; for 1921 they are about \$100,000 more than for 1920, and, in total, amount to more than two 25c. dividends per year. A dividend of 25c. per share was declared payable on November 1 to stockholders on record on October 10.

MONTYRE-PORCUPINE MINES, LIMITED

Report for the year ended June 30, 1921.

Property: Mines and mill at Schumacher, Ontario, Canada.

Operating Official: R. J. Ennis, general manager.

Financial: Earnings, \$1,904,326.36; operating costs, \$1,088,763.83; non-operating revenue, \$272,951.91; net profit for the year, \$815,530.12.

Development: 8281 ft.; diamond-drilling, 8464 ft.; ore-reserves, estimated, 624,422 tons, assaying \$10.25 per ton.

Production: 171,916 tons was treated of an average value of \$11.67 per ton. Bullion containing 91,330.26 oz. gold and 19,806.40 oz. silver was recovered.

General: It is stated that the increased quantity of carbonaceous ore in the mine made the problem of finding a successful method of milling of considerable importance. Experimental work and a study of the question has resulted in the development of a process that will treat satisfactorily the ore and without the aid of flotation. After a preliminary treatment in the ball- and tube-mill circuits the ore can be sent to the cyanide plant without danger of premature precipitation of gold.

Fluorspar and Cryolite in 1920. By Hubert W. Davis. II:9, U. S. Geological Survey, 1921. 16 pp. From Mineral Resources of the United States, 1920, Part II.

Arsenic, Bismuth, Selenium, and Tellurium in 1920. By Victor C. Heikes. I:7, U. S. Geological Survey, 1921. 22 pp. From Mineral Resources of the United States, 1920, Part I.

Gold, Silver, Copper, Lead, and Zinc in Arizona in 1919. Mines Report. By V. C. Heikes. I:16, U. S. Geological Survey, 1921. 40 pp. From Mineral Resources of the United States, 1919, Part I.

Gold, Silver, Copper, Lead, and Zinc in the Eastern States in 1920. Mines Report. By J. P. Dunlop. I:2, U. S. Geological Survey, 1921. 9 pp. From Mineral Resources of the United States, 1920, Part I.

The Mineral Industry of the British Empire and Foreign Countries. War Period. Cobalt. (1913-1919). Imperial Mineral Resources Bureau, 1921. 22 pp. For sale by H. M. Stationery Office, Imperial House, Kingsway, London, W.C. 2, England. Price, 9d. net.

A Geological Reconnaissance of the Tucson and Amole Mountains. By Olaf P. Jenkins and Eldred D. Wilson. With Notes on the Southern Section of the Amole Mining District. By Milton A. Allen. Bull. 106, Geological Series No. 2, University of Arizona, Tucson, Arizona, 1920. 24 pp., index, ill., maps, diagram.

Book Reviews

Oil-Field Practice. By Dorsey Hager. 310 pp., ill. McGraw-Hill Book Co., New York. For sale by the 'Mining and Scientific Press'. Price, \$3.

A growing demand for a book dealing with American methods of developing oil properties has led to the production of the present volume, which is a companion book to 'Practical Oil Geology', by the same author. The facts and methods given in the present volume represent a compilation from authoritative sources, supplemented as far as possible by first-hand information. The author, in the first chapter, makes general observations and discusses historical data. The scope and the life of the industry are followed by speculations as to the future price of oil and future markets. Monopolies in the oil business are discussed, with particular reference to the Standard Oil group of companies. In the second chapter the question of the acquisition of oil lands is considered, with notes on royalties, titles, size of acreage, and other essential details. Development drilling is discussed in the next two chapters, followed by an analysis of production methods. Chapter VI deals with transportation, storage, and fires; and Chapter VII with avoidable oil-field wastes and losses. Refining methods are described and illustrated by means of excellent charts. The book concludes with a chapter on the elements of valuation and a useful appendix of tables and forms; it has been produced in a style that characterizes many useful handbooks issued by the McGraw-Hill Book Co., and will be found of value to all who are in any way interested in the petroleum industry.

Introduction to the Study of Minerals and Rocks. By A. F. Rogers. 527 pp., ill., pocket size, flexible. McGraw-Hill Book Co., New York. For sale by the 'Mining and Scientific Press'. Price, \$4.

The author, who is Professor of Mineralogy at Leland Stanford University and an associate editor of the 'American Mineralogist', as well as the publishers, are to be congratulated on the appearance of a second edition of an attractive and reliable text-book on the subject. It was prepared primarily to cover a year's work in the study of minerals and rocks, and has been arranged for use both in the classroom and in the field. Part I deals with the chemical, morphological, and physical properties of minerals. Part II contains the description of 175 minerals; these include all the common minerals and most of those of any special economic, geologic, or scientific importance; large type is used to distinguish 56 of the commonest types. The order of the minerals is almost the same as in Dana's 'System of Mineralogy', except that the silicates are placed last. Part III contains an elementary discussion of the occurrence, association, and origin of minerals. This includes a brief description of some of the more common and important rock types and also of the prominent classes of veins and replacement deposits. Appended to Part IV there are two tables for the determination of minerals. A glossary of terms not explained in the text has been included in the Index.

Determinative Mineralogy. By C. H. Warren. 163 pp., ill. McGraw-Hill Book Co., New York. For sale by the 'Mining and Scientific Press'. Price, \$2.

This manual was originally written and privately printed for use in the beginner's course in mineralogy at the Massachusetts Institute of Technology, where the author is Professor of Mineralogy. It is pointed out that there are several excellent text-books covering elementary crystallography and descriptive mineralogy that are satisfactory in

these particulars. On the determinative side, however, they leave much to be desired. It was, therefore, in order to enable the student to supplement his descriptive text-book that this manual was compiled. Experience with its use, over a period of several years, has demonstrated that it gives satisfactory results both as an aid in the determination of the more common minerals and as a means of training the students in the systematic examination of mineral material generally. The contents are as follows: I. Use of the blowpipe. II. Simple tests for the elements. III. Tabulated list of reactions that are useful in determinative mineralogy. IV. Determination of minerals, use of tables, etc. Index.

American Chemistry. By H. Hale. 215 pp., ill. D. van Nostrand Co., New York. For sale by the 'Mining and Scientific Press'. Price, \$2.

Chemistry is constantly becoming of greater importance in the life of the American people, and the realization of its value has been deepened during recent years. This situation, as the author points out, calls for a simple and clear statement of the more outstanding facts of American chemistry, which is the purpose of this book. It seeks to be of service both to the general reader and to the student still in school. For the latter it is intended for use either as collateral reading, together with a course in general chemistry, or as a short separate course. Two objects have been sought: to call the attention of the reader to the fundamental importance of chemistry to America, as well as to the wonderful chemical possibilities in America; second, to encourage in him the habit of reading articles in current literature that have a bearing on chemistry, to which frequent references are given. The record of the American chemist is one of achievement; it furnishes a real basis for future progress. The book is interesting and instructive. It deals with war chemistry; water and sewage; sanitation and medicine; food and fertilizers; textiles; coal-tar and dyes; fuel; silicate industries; paints and varnishes; rubber; electro-chemistry in industry; acids; metals; and American chemistry and the future.

Agricultural Geology. By the late F. V. Emerson. 319 pp., ill. John Wiley & Sons, New York. For sale by the 'Mining and Scientific Press'. Price, \$3.

Geology and agriculture are closely related; indeed it is due to geological processes that hard rocks are broken down to soil, and essential mineral substances are set free that in some cases affect the physical qualities of the derived soil, and in others serve as sources of plant food. The student of agriculture, therefore, should have at least an elementary knowledge of the processes and principles of geology, with especial reference to the geology of soils and fertilizers. With this object in view, states Dr. H. Ries in a foreword, the late Professor Emerson prepared the present volume, but unfortunately his untimely death prevented his seeing it through the press. The subject matter and mode of treatment are the outgrowth of some years of experience in teaching geology to agricultural students; and although the book was prepared primarily for class-room use, it was also the author's hope that it might prove serviceable for reading and correspondence classes. On this account he endeavored to make the treatment as untechnical as possible, without sacrificing scientific accuracy. The book is excellently illustrated, and is a credit to the author and the publishers. The contents are as follows: Introduction. I. Minerals. II. Rocks. III. Weathering. IV. Residual soils from various rocks. V. Wind work and eolian soils. VI. Ground-water. VII. Streams and their work; alluvial soils. VIII. Classes of alluvial deposits. IX. Soil creep; colluvial soils. X. Gla-

ciers and glaciation. XI. Lakes and swamps; lacustrine and cumulose soils; lakes. XII. Oceans. XIII. Mineral fertilizers. XIV. Soil regions in the United States. XV. Historical geology. Appendix; soil maps.

Motor-Truck. By V. W. Page. 962 pp., ill. Norman W. Henley Publishing Co., New York. For sale by the 'Mining and Scientific Press'. Price, \$5.

As stated in the preface, this volume has been prepared to meet a demand from motor-truck owners, users, and drivers, especially those charged with operation and mechanical care, for a text-book that would outline the principles on which trucks of various types operate. The treatise not only considers the construction and operation of all the leading types of gasoline and electric trucks, but also gives valuable data on systematic maintenance and cost control that will prove invaluable to those charged with the responsibility of operating truck-fleets economically and efficiently. Through the co-operation of the service departments of the leading American motor-truck makers, the author has been enabled to publish considerably more practical operating- and repair-data than are usually found in a treatise of this character, and also to present a series of informative drawings and photographs. The contents of the book are as follows: I. Motor-truck types. II. Motor-truck power-plant. III. Motor-truck fuel and carburetion systems. IV. Truck-motor cooling and lubrication. V. Motor-truck electrical-system. VI. Motor-truck clutch and gear-box. VII. Motor-truck drive-systems. VIII. Motor-truck chassis parts. IX. Motor-truck loading and operation. X. Special truck applications and body designs. XI. Road troubles and truck-maintenance. XII. Gasoline-truck repair, and adjustment. XIII. Electric-truck construction. XIV. Construction, care, and charging of truck-batteries. XV. Driving and maintenance. XVI. Truck operating cost determination.

Drawing Room Practice. By F. A. Stanley. 253 pp., 6 by 9, ill. McGraw-Hill Book Co., New York. For sale by the 'Mining and Scientific Press'. Price, \$2.50.

It has been the observation of the author, who is the editor of 'Western Machinery World', that young draughtsmen, and even many shop-men of experience, find it difficult to visualize a piece of work yet to be completed in wood or in metal; in instructing such men in mechanical drawing it has been found desirable to put before them either a casting or a forging, representing the object to be drawn; or, where this is not feasible, as is ordinarily the case, to use photographic views that show the appearance of the work as it is to be when finished. The satisfactory results obtained have led to the gathering of a wide variety of material, together with actual working-drawings of such parts for use in specific chapters of the book, which deals with the making of drawings, from the simplest constructions to complete assembly and working-drawings of various classes.

The laying out of jigs and fixtures, punches and dies, and other special tools forms an important part of the work of the modern drawing-room; the draughtsman wishing to develop in his profession must familiarize himself with approved methods of showing such tools in his drawings. Systems of limits and tolerances for dimensions have already been adopted or are being adopted in the plants manufacturing parts in quantities; and here again many draughtsmen, even of wide experience, must add to their knowledge by a study of methods of limit dimensions adapted to their own particular line of work. The contents of the book are as follows:

I. Drawing Instruments and their Uses. II. Projection. III. Practical Applications of the Principles of Projection. IV. Development of Surfaces—Intersections. V. The Helix

and its Application. VI. Screw Threads and their Conventional Forms. VII. Detail Parts—Sections. VIII. Parts and Sections of Assembly Drawings. IX. Working Drawings. X. Working Drawings of Small and Medium-Size Parts. XI. Tool Drawings. XII. Limit Dimensions of Drawings. XIII. Isometric and Oblique Drawings. Shop Sketches. Index.

America's Power Resources. By C. G. Gilbert and J. E. Pogue. 326 pp., ill. The Century Co., New York. For sale by the 'Mining and Scientific Press'. Price, \$2.50.

This book is the result of an attempt to interpret the special, though generally unrecognized, importance attached to the resources of energy—coal, oil, gas, and water-power. The authors discuss the inefficient manner in which these are utilized. The material presented is largely the result of investigations that were carried on in the Smithsonian Institution, in the Fuel Administration, and in a somewhat diversified engineering practice, and brought out from time to time as special papers, emanating mostly from the Division of Mineral Technology, U. S. National Museum. "It is not," say the authors, "beyond the bounds of reason to foresee a condition whereby a householder, in place of his ton of anthracite, will receive a ton of smokeless coal without slate, a month's supply of cooking-gas, forty 'miles' of motor fuel, enough fertilizer to start a small garden, and tar sufficient to lay the dust in front of his house—all for far less money than he now pays for inferior coal." Municipal fuel plants are suggested. Discussing water-power, the author says that "It is cheaper for the user of energy to rely on the transportation facilities already at hand, employing them in the movement of the crude bulky material, than to provide himself with special facilities for the transmission of the refined electric derivative; but it does not follow because this procedure is individually cheaper that it is economically preferable. In the absence of railway facilities, for example, it would be decidedly cheaper for the individual consumer to haul his coal from the nearest mine than to build a railway for the purpose. Yet no one would think of arguing that reliance upon truck haulage would be preferable to the opportunities that would be afforded by railway transportation. The issue between electric transmission and railway haulage is precisely similar". The contents of the book are as follows: I. Human labor and mechanical work. II. The foundations of industrialism. III. Coal, the basis of national welfare. IV. Oil, the acceleration of progress. V. Natural gas, Nature's bonus to America. VI. Water-power, an unused annuity. VII. Smokeless fuel and civic progress. VIII. Power and industrial progress. IX. Three-dimensional transportation. X. The equalization of industrial opportunity. XI. Co-ordination and industrial evolution.

Graphical Methods. By W. C. Marshall. 245 pp., ill. McGraw-Hill Book Co., New York. For sale by the 'Mining and Scientific Press'. Price, \$3.

Graphic methods comprise all the methods of representing the relations of objects or facts by means of the relations between the lines of a diagram; all devices for representing by geometrical lines the numerical figures that result from the quantitative investigation of phenomena are included under the title. Graphic methods are employed to a large extent in physical investigations, as aids to calculation and for the purpose of exhibiting the nature of the law of variation of sundry phenomena. The principal use of these methods is to show the mutual variation of two quantities, as evidence by (1) the conveying of information, as when parallel lines of different length are exhibited that are proportional to the population of different countries or to the

population of one country at equal periods of time, and (2) to aid numerical or logical calculations, as when a curve is drawn through points whose co-ordinates represent the population of a country at successive decadal intervals, this curve being used to ascertain the population at other dates. We learn that there are three classes of graphic methods: (1) those that make no use of the continuity of space except to show that the extremities of lines are connected, (2) those that use only the projective properties of space such as drawings and maps, and (3) those that use only the metric properties of space and produce diagrams intended to be measured. Any quantity susceptible of mensuration can be represented graphically by a straight line, the length of which corresponds to the value of the quantity. Addition, subtraction, multiplication, and division of pure numbers are easily carried out graphically by means of lines; the application of this principle is found in the slide-rule. Graphic methods have great value in the interpretation of tables and the solution of formulæ, because of the ease of drawing a line, the cheapness of paper and pencil, and the skillful judgment of the human eye. The representation of quantities on paper is a convenient way of placing them before the eye and of comparing them. The simplest application is seen in the representation of tabular data, such as statistics. Engineering periodicals, technical books, newspapers, and text-books contain an endless variety of charts, good and bad, clear and complex, useful and useless. The word 'monography' means nothing to the average man, but it is of great importance in graphic chart-making; every technical man should know its possibilities, and be able to apply its principles. The present volume will serve as a means of instruction. The contents are as follows: I. Introduction. II. Kinds of graphs. III. Making of diagrams. IV. Applications. V. Determination of laws. VI. Routing and organization. VII. Calculations. VIII. Nomography. IX. Mechanical graphical records. Bibliography.

Waste in Industry. By the committee on the elimination of waste in industry of the Federated American Engineering Societies; with a foreword by H. Hoover. 402 pp. McGraw-Hill Book Co., New York. For sale by the 'Mining and Scientific Press'. Price, \$4.

In January 1921, Herbert Hoover, as president of the Federated American Engineering Societies, named a committee of engineers to make a study of waste in industry. The report of that committee was duly presented a few months afterward; it is now re-printed in book form. It covers six industries—the building trades, men's ready-made clothing, printing trades, metal trades, boot and shoe manufacturing, and textile manufacturing. In addition to these six specific field studies, seven reports of a statistical character were prepared, each of them dealing with some aspect of industrial waste, or its elimination on an extensive or nation-wide basis; these form the third section of this report. As Mr. Hoover points out in the foreword, "We have probably the highest efficiency and ingenuity in the operation of our industries of any nation. Yet our industrial machine is far from perfect. The wastes of unemployment during depressions; from speculation and over-production in booms; from labor-turnover; from intermittent failure of transportation of supplies of fuel and power; from excessive seasonal operation; from lack of standardization; from loss in our processes and materials—all combine to represent a huge deduction from the goods and services that we might all enjoy if we could do a better job of it". The contents of the book are as follows: Part I. Summary of detailed reports: I. Introduction. II. Sources and causes of waste. III. Recommendations for elimination of waste. IV. Description of questionnaire and evaluation. Part II. Engineers'

field reports: V. Building industry. VI. Men's clothing. VII. Shoe manufacturing. VIII. Printing. IX. Metal trades. X. Textiles. Part III. General reports: XI. Unemployment. XII. Strikes and lockouts. XIII. Legal machinery for adjusting disputes. XIV. Industrial accidents. XV. Health of industrial workers. XVI. Eye conservation. XVII. Purchasing and sales policies.

Within the Atom. By John Mills. 215 pp., ill. D. van Nostrand Co., New York. For sale by the 'Mining and Scientific Press'. Price, \$2.25.

This is another book by the well-known author of 'The Realities of Modern Science', who explains that it deals with theories as to matter and energy without mathematical formulation, emphasizing the granular structure and the electrical nature of matter and the apparently corpuscular character of energy. The reader need have no previous knowledge of electricity, mechanics, or chemistry. Some knowledge of electricity, however, is required for the appreciation of the evidence of certain critical experiments upon which modern scientists base their belief in electrons and in quanta of energy. To supply this in a quick and easy manner, the usual historical order of presentation has been abandoned, and the correctness of modern theories is assumed at the start. The electron and the proton are postulated; in terms of these the author then describes those few phenomena of electricity that are essential to the later consideration of the evidence. Thus is hoped most rapidly to introduce the reader to modern theories as to the invisible workings of the physical universe. The following topics are dealt with: I. Atomic structures. II. Satisfied and unsatisfied systems. III. The Periodic Table of atomic systems. IV. Mass and inertia of atomic systems. V. Radio-active disintegrations. VI. Conduction of electricity through gases. VII. Conduction through solids, and other electrical phenomena. VIII. Proof of the existence of the electron. IX. Isolating a proton. X. X-rays and atomic numbers. XI. Photo-electric effects and the quantum of energy. XII. Light radiation and atom-molecules. XIII. Quantum hypothesis. XIV. Energy and its availability. An excellent glossary is appended.

Anuario de Minería, Metalurgia, Electricidad y demas Industrias de Espana, 1921. By Adriano Contreras, Roman Oriol, and Lois Oriol. Published by the 'Revista Minera', Villalar 3, Apartado 260, Madrid, Spain. 1010 pages. Not for sale in the United States. Price, 10.50 pesetas in Spain.

This is the twenty-first edition of a well-known directory, which has been compiled by an ex-professor of the School of Mines of Madrid. It contains a list of the mines of Spain, classified according to Province, together with the mining, metallurgical, electrical, and chemical societies in the country, with names and addresses of mining engineers and other information. It also contains details with regard to custom-house duties and commercial treaties. It will be found of value to anyone who is interested in the mining and metallurgical industries of Spain.

Silver Ores. By H. B. Cronshaw. 152 pp., paper. John Murray, Albemarle street, London, W. Price, 6s.

This is one of the series of monographs being prepared under the direction of the Minerals Resources Committee of the Imperial Institute. It consists largely of a résumé of the available information on the subject and will be found invaluable as a book of reference. The first chapter deals with silver ores, their occurrences, characters, and uses; then follows detailed descriptions of the character and locations of silver ores in all parts of the world, arranged in geographical order. A map of the silver deposits of the world is included, as well as a comprehensive list of references to the literature of the subject.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

NEW TYPE OF BELT-DRIVEN AIR-COMPRESSORS

The Ingersoll-Rand Co. has announced a new line of belt-driven air-compressors. This type is known as the 'Imperial' Type 'XCB'; incorporated in it are several noteworthy fea-

Section Through Cylinder and Intercooler of 'Imperial' Type 'XCB' Compressor, Showing Clearance-Valve and Pockets

tures of construction, including Ingersoll-Rand plate-valves, for both the air intake and discharge, and the 5-step clearance-control for regulating the compressor's output.

The plate-valves used in this compressor have been per-

Ingersoll-Rand 'Imperial' Type 'XCB' Compressor with Short Belt-Drive

fectured after a most complete analysis of the light-weight plate-type valve. They include the features which have been proved necessary to the successful functioning of this type of valve, the most important of these being that the

valve is supported throughout its entire operation in perfect alignment without any form of wearing guide—an essential feature in the life of the valve.

The clearance-control is a method of securing extremely efficient operation at part loads. Under average working conditions it is a well-known fact that the demand for air is seldom steady throughout the working day, and for this reason the performance of the compressor at underload is of primary importance.

With the clearance-control the compressor is automatically loaded or unloaded in five successive steps, these steps being obtained by the reduction or addition of clearance-space to the air-cylinders. The compressor will operate at full-, $\frac{3}{4}$ -, $\frac{1}{2}$ -, $\frac{1}{4}$ -, and no-load, and the design of the clearance-control is such as to secure efficient operation at any one step, the reduction in input-power required being practically in proportion to the reduction in output capacity.

The entire control is automatic. If the compressor is operating at full load and the demand for air falls off, this control automatically causes the compressor to operate at one of the underload points. When the demand for air is increased the compressor automatically assumes the load in successive steps.

An extremely valuable feature of the clearance-control is the fact that the clearance-pockets are made integral parts of the compressor cylinder and the entire regulation is obtained by the control of the volume of air taken in and compressed.

Another added feature of this control is the maximum-demand stop, which will prevent the compressor being operated at any higher maximum load than is desired. This can be adjusted so that the compressor will operate on a maximum of $\frac{1}{4}$ -, $\frac{1}{2}$ -, $\frac{3}{4}$ -, or full-load and, under conditions where the load-factor is comparatively low, it is of value in reducing the maximum demand, permitting a saving in the purchase of electric power—a feature found in no other type of control.

With the clearance-control, reduction in power required will be in proportion to reduction in output capacity. All the mechanism for regulating the compressor is independent of the compressor running-gear. The loading and unloading of the compressor is automatically accomplished in steps, the difference between any two steps being small enough to prevent any undue electric-current fluctuation.

This new type of belt-driven compressor, equipped with clearance-control can be furnished single-stage for low pressures and two-stage for higher pressures. The piston-displacement capacity for 100 lb. discharge-pressure ranges from 610 to 1505 cu. ft. of free air per minute.

'Imperial' Type 'XCB' compressors can also be furnished with the well-known short-belt drive-attachment with floating idler. This method of drive is now well known to all users of compressors, who acknowledge its advantages in saving floor-space, saving in length of belt, and permitting a greater arc of belt contact.

The Ingersoll-Rand Co. also announces its new Bulletin No. 3042, in which this new type is described in detail.

HAMMER-WELDED STEEL PIPE

The process of making lap-weld pipe by hammer-welding is relatively new as compared with the butt-weld and lap-weld processes, and the sizes made by hammer-welding are, relatively, much larger in diameter.

The pipe is made by bending a steel plate into tubular form with edges overlapping and then welding the overlapped edges, after they have been heated, by hammer-forging them on an anvil-block supported on a horn inside the pipe.

The process of hammer-welding is particularly well adapted to the manufacture of pipe in sizes from about 24 to 96 in. Due to the simplicity of manufacture—in that rivets, projecting ribs, and other objectionable features are eliminated—hammer-weld pipe has a relatively high efficiency. The strength and ductility of the material, the sound and smooth-welded seam, the simple and efficient types of joints that can be used, and other advantages make hammer-weld pipe particularly desirable for almost any purpose requiring large-diameter pipe.

With the addition of these larger sizes to the complete line of tubular products up to 30 in. diam., the National Tube Co. is now in a position to meet practically all wrought tubular requirements, with a total range of sizes from $\frac{1}{4}$ to 96 in., inclusive, and can recommend the best type of pipe for each particular installation.

'National' hammer-weld pipe is adapted for practically all purposes where large-diameter pipe is required. Its larger fields of service are for water, gas, steam, and various types of pumping or power-plant installations. This pipe is particularly adapted to the higher-pressure requirements because of its dependable strong weld, its low-friction resistance to flowing liquids or gases, and to the fact that the hammer-forged weld is superior to any other form of jointing in its resistance to stresses caused by expansion, contraction, or other forces. Hammer-weld pipe is also adapted to the construction of tanks, shells, retorts, stills, digesters, receivers, etc. Bulletin No. 13, just issued by the National Tube Co., is a comprehensive treatise on the purposes and advantages of pipe of this character.

COMMERCIAL PARAGRAPHS

The U. S. High Speed Steel & Tool Corporation has developed the 'Eurekast' detachable rock-drill bit for which it claims 83% greater driller distance as compared with the standard bit of Swedish steel. The speed of drilling is not lessened. The bit is connected to the bar of steel by means of a threaded sleeve union; it is made of vanadium steel.

The Powdered Coal Development Corporation has been organized with headquarters at Omaha, Nebraska. This company controls the Pruden patents for the burning of pulverized coal in the western half of the United States. The company is actively engaged in financing and erecting central pulverizing plants and installation of equipment for burning pulverized coal. Byron B. Oberst, formerly with the Interstate Oil & Refining Co., is president of the new corporation.

The second official approval of a storage-battery locomotive for use in gaseous mines has just been issued by the United States Bureau of Mines to the Jeffrey Manufacturing Co., of Columbus, Ohio. The approval covers a six-ton storage-battery locomotive, which may be equipped with a battery consisting of either 80 type A-S Edison cells or 48 Type MV 21-plate Iron-Clad Exide cells. Caustic potash is specified as the electrolyte for use with the Edison battery.

Catalogue V-101, issued by the Pittsburgh Mining Machinery Co., of Pittsburgh, Pennsylvania, describes and

illustrates the company's centrifugal and disc fans for use in mine ventilation. A feature of the centrifugal fan is that no special cut-off is provided, required, or permitted to force delivery of the air. Delivery is obtained without such arbitrary device, by the scientific scroll of the housing, the shape of blades, and angle at which they are set. This fan with 10-ft. wheel is capable of delivering 300,000 cu. ft. of air at 5-in. static pressure or water-gauge.

The American Turpentine & Tar Co., of New Orleans, one of the oldest and largest producers of distilled pine products, will hereafter participate in the marketing of its products. Due to its location upon the Mississippi river, where freight-rates divide, the company is able to ship directly upon Western railroads, thereby expediting deliveries and greatly lessening freight-costs. For shipment to Mexico, South American, and Pacific Coast points direct steamship lines are available. Shipments will be made in tank-cars, barrels, steel drums, or cases containing two 5-gallon cans. A small booklet, called 'Destructively Distilled Pine Flotation-Oils', has just been issued.

The Bucyrus Co. announces the removal of its New York office to suite 728, 30 Church St., with E. G. Lewis in charge as Eastern sales-manager, effective December 1. Mr. Lewis has for many years been connected with the sales organization of the company both at Chicago and New York. M. J. Woodhull, who has had large experience in the manufacture and sale of railroad-construction equipment with the Bucyrus Co., is appointed Central sales-manager to succeed Mr. Lewis. He will be in charge of the Chicago office, 622 McCormick Bldg. E. R. Weber is appointed Northern sales-manager, at Minneapolis, 1224 McKnight Bldg., to succeed J. N. Gawthrop, who will become associated with Mr. Lewis in New York.

The Timken Roller Bearing Co., in line with its program of expansion, has just entered a new field—that of mine equipment. The salient parts of Timken bearings that have caused their universal adoption in front wheels as well as other points of hard service in automobiles, trucks, and tractors, appeal to mine operators as a solution of the wheel-bearing problem in mine-car service. Due to the tapered feature, the Timken bearing carries both radial- and thrust-loads and all combinations of both, and when, after long and severe service, wear develops, a slight adjustment eliminates it at once. These bearings have exceptional capacity per unit of space required for installation; therefore, are more economical than other types. The bearings are easily mounted in the wheels and ample space is provided for packing with lubricants so that mine-car wheels should not require attention for lubrication or adjustment for a period of from one to two years of hard service.

The Monroe Calculating Machine Co., Woolworth Bldg., New York, has just brought out a new model calculating machine to be made up in three sizes 12-, 16-, and 20-place capacity. This wide range supplies a machine for every need. Calculation with speed and practically without effort is made possible by the easy flexible crank-operation of the Monroe. The crank is short, smooth running, and turns with merely a slight wrist movement. Combined with the smooth easy turn of the crank is a feature making crank operation simple in the extreme. A forward or backward turn is completed at the same point, the natural position, and, although a wide leeway is allowed, the mechanism is absolutely locked against error or change during the turn of the crank. When the work is done and the answer noted, no time is wasted in the clear-out. Simply a reverse turn of the small clear-out crank raises the carriage and clears the dials simultaneously. A forward turn clears the upper dials. Other features make for speed and accuracy.

T. A. RICKARD, Editor

MR. ROY C. OSGOOD, in his annual address as president of the Investment Bankers Association, stated: "Business has turned the hardest corner in your experience and is pulling steadily on the upgrade". He ought to know.

EXCELLENT progress is being made by the Disarmament Conference at Washington. Our Thanksgiving this year will include a deep feeling of gratitude that the leaders of the nations have been restored to political sanity and are responding to the urge of public sentiment in every civilized country. All the trumpery memorials erected to the dead who died in battle will be superseded worthily by the recognition of the futility of warfare.

IN our last issue we published a short review on the report upon 'The Elimination [meaning prevention] of Waste in Industry' prepared for the Federated American Engineering Societies by a committee appointed by Mr. Herbert Hoover, as the first president of the federation. This report has been issued as a book of 350 pages, rich in facts of an informing kind. The most striking feature of the findings handed down by the 18 engineers constituting the committee is the preponderant share of responsibility for waste that is attributed to defective management. In the six industries that were studied the responsibility for waste "assayed against management" ranges from 50 to 81%, and averages 68%, whereas the proportion of responsibility imputed to labor ranges from 9 to 28%, and averages only 16%. That may be one reason why the directors of one of the Federated Societies, namely our own Institute of mining engineers, passed a resolution disapproving of the report of this committee.

TWO interesting points in mine taxation were decided on November 15 by Judge Page Morris, sitting in the United States District Court of Utah, in the suit of the South Utah Mines & Smelters Company v. Beaver County. The South Utah company, operating at Newhouse, in Beaver county, had accumulated prior to 1914, when operations were suspended, a large dump of copperbearing tailing from its concentrator. During 1918 the Utah Leasing Company earned net proceeds of \$120,547 from treating a portion of this tailing in a flotation plant erected specially for that purpose. Pursuant to the provisions of an amendment to the constitution of Utah, passed in 1918, Beaver county in 1919 placed an assessment against the South Utah company, on a valuation of \$361,641, or three times the value of the net proceeds of the leasing company for the preceding year. The South Utah company paid the tax under protest and started suit to have the assessment set aside. Two reasons for annulment were advanced: first, that the market-value of the property was not taken into consideration and that the procedure of determining valuation by using a multiple of the net proceeds was unconstitutional; and second, that the contract under which the lessee operated constituted a sale of the dump, and that accordingly any valid tax should be levied against the Utah Leasing Company. With respect to the second contention, the Court held that the contract merely gave the lessee the right to extract the metals from the dump in consideration of a stipulated division of any profits from such operations. Both questions were decided against the South Utah company. Although Judge Morris said that he had no hesitation in deciding the matter of constitutionality so as to uphold the basic law of the State, he recognized weighty arguments against the method of assessment, and suggested that the litigants might well take the case to the Supreme Court of the United States, in order to settle the point.

ON another page we publish some reminiscences of early days on the Comstock by Mr. Richard H. Stretch, who is now living at Seattle. Mr. Stretch is an octogenarian with mental faculties in good trim, as is shown by his delightful story of the olden time. We happen to know that he was born in Cheshire, England, and came to this country at the age of 24, in 1861. At that time his chief scientific interest was in insects; he was a keen entomologist, and he was eager to travel in new countries in pursuit of his hobby. So, in 1861, he went on a visit to an uncle in Illinois, traveling by way of New York and New Orleans. Two years later he joined an emigrant party bound for California, and won a reputation among the Indians because one of them had found a bottle that Mr. Stretch had lost containing insects in alcohol. When the friendly Indian saw other parts of his collection, he was greatly impressed and passed the word along that a Big Medicine Chief was on the way. This, it is said, saved the party from attack.

Mr. Stretch went to Virginia City and there began his connection with mining, as related in the article.

SUBSTITUTES are sometimes 'just as good' as the original; often they are expensive in the long run, regardless of the apparent saving in first cost. One of our readers recently recounted an experience in this connection. He was furnishing a newly acquired home. Having a bay-window in one of the rooms, he made the necessary measurements, purchased the fittings required, and sent to a local hardware store for two lengths of $\frac{3}{4}$ -inch brass rod to carry the window-curtains. The rod arrived; but in trying to bend it to conform to the angles of the window a great deal of difficulty was experienced. This led to an examination, which disclosed the fact that it was made of iron, afterward brazed. Several ineffectual attempts were made with home tools, the rods being sent finally to a local novelty-shop to be fashioned according to requirements. There they were heated to such a degree that the brazing was destroyed. It cost the victim 50 cents to have four right-angle bends made on the two light-iron rods, during which the appearance of the rods was spoiled, and subsequent loss and damage from rust were accepted as inevitable. The net result of the substitution of iron for brass was that a job was found for a mechanic, the hardware merchant apparently made an exorbitant profit on an article that gave no satisfaction, the victim was disheartened, and will avoid the use of metal in future for similar requirements. He had to pay an absurd price for the iron; the veneer of brass was valueless, for it had to be destroyed before the rod could be bent to the required angle. The total cost of the finished article was out of all proportion to the result. Is the Copper and Brass Research Association, before taking action, waiting for an improvement in the demand for copper and copper alloys? If so, it is making a big mistake. There is little hope of regaining the trade later if brass, at the present price of copper, cannot compete now with iron for the manufacture of a large number of articles. An educational propaganda is needed, but the public requires little advice or suggestion on the subject; it is the hardware dealer and the retailer that must be shown that they are 'killing the goose'. Those interested in the sale of iron are alive to the importance of intensive action; just now they are getting exorbitant prices for their metal in manufactured form, largely because the copper and brass dealers insist on even more exorbitant prices. There are drawbacks to the use of iron, but all of them are not insurmountable; non-corrosive iron has made its appearance; it contains chromium, as does the so-called 'stainless steel', although in smaller quantity; it is being used for the manufacture of a large number of articles previously made of brass. Unless the Research Association bestirs itself, the copper mining industry when it resumes operations will find that serious inroads have been made into its prospective business by the substitution of cheaper materials during a period when concerted action should have been taken to familiarize the public and the dealers

alike with the advantages of articles that are made of copper and brass. What is needed is a little less 'research' and a little more action on the part of the Association; perhaps a change of name would help; its aim is commercial, not scientific.

CONTRIBUTIONS to 'Discussion' in this issue cover a variety of topics. That the proposed revised mining law favors the large operator and discriminates against those who are interested in the search for and the development of mineral deposits is claimed by Mr. H. D. Phelps, of Prescott, Arizona. He cites other objections, and makes a plea for amendments and additions to the present laws, rather than the replacement of them by the proposed enactment. Relief for the gold miner, by means of the McFadden bill, is urged by several contributors. Mr. E. E. Putnam writes from Mammoth, Arizona, and mentions the sorry plight of aite, vanadinite, and deseloizite. Mr. Putnam says that was as productive to its owners as it was interesting to the geologist and to the mineralogist. The Mammoth is known to collectors for its beautiful specimens of wulfenite, vanadinite, and deseloizite. Mr. Putnam says that many gold mines are being kept alive by the hope that the McFadden bill will be passed by Congress, and that, should this measure of relief be denied, these mines will be shut-down. He assumes that the present increase of interest in gold mining is due to the expectation of benevolent legislation, but in this we differ from him. It is our opinion, which we proffer in as sincere a spirit as Mr. Putnam does his, that the general public has discounted the prospect of such special legislation, and is becoming increasingly interested in this branch of metal mining because it realizes that conditions are becoming more favorable to it, in consequence of the fall in the cost of labor and supplies. The fixed price of gold is re-asserting itself as a factor favorable to the mining of ore deposits containing the standard metal. We deplore, with Mr. Putnam, the lessened use of both gold and silver, but we anticipate confidently that both will come into their own in due course, and that the paper currencies of Europe will be replaced eventually in large measure by silver coinages. We sympathize with Mr. S. J. Kidder, of New Mexico, in his reference to the use of gold in arts and manufactures, and the purchase of gold for such purposes at a price far below the cost of current production, but such anomalies and unfairnesses are common. We have paid 14 $\frac{3}{4}$ cents per pound for the paper on which the 'Mining and Scientific Press' is printed, whereas we used to pay 4 cents for paper of better quality before the War. Of the increase only a third is legitimate; the rest is profiteering; yet we do not expect Congress to legislate in behalf of ourselves and other publishers similarly circumstanced. The producers of war minerals were compensated because they prevented a shortage in response to the urging of the Government; the gold producers, as Mr. Kidder suggests, were in the same category; they also were told that their productivity was essential to the national pur-

pose. Presumably gold was not included among the war minerals because the market-value of it, in the United States, did not suffer by the termination of the War. In reply to Mr. J. S. Taylor, of Oregon, we can only say that the mining of gold is not superior to the law of supply and demand, although the operation of that law is obscured in this case by reason of the fact that the price of gold is fixed by law; nevertheless the market-value of gold in terms of commodities varies in accord with the supply and demand of those commodities. We venture to add our conviction that the whole intricate and vexatious question of gold as a standard of value is international in its bearings, and that the time must come when it will be submitted to an international conference. No single nation can legislate successfully on the subject. Mr. Alfred T. Fry makes interesting comments on dry crushing in ball-mills, and submits screening analyses from which it may be inferred that fine powder remains in suspension in the mill and so escapes further comminution. This may be desirable in some instances, but in the case in point it was a disadvantage, for the problem was to crush the material so that only 5% remained on 150-mesh, and this was found impracticable, regardless of the time taken or of the conditions maintained in regard to load of pebbles or balls. Mr. Thomas French, a Canadian metallurgist, adds an interesting item to the known history of the cyanide process, with particular reference to the use of charcoal as a precipitant of gold from cyanide solution during the early days of the application of the MacArthur-Forrest invention.

Steel From Western Iron Ore

If negotiations now in progress in San Francisco are successful a new era in the development of Western industry is close at hand. Utah and California are particularly concerned; the plan is to form a \$20,000,000 corporation in which will be merged a number of companies that control coal mines and iron-ore deposits in Utah, and two others that own and operate steel plants in both northern and southern California. It is proposed to erect blast-furnaces at Salt Lake City and to ship the pig-iron produced to the Californian plants, where it will be converted into steel and rolled into shapes. More explicitly, the enterprise includes the following projects: (1) the increased development of the mines of the Utah Coke & Coal Company in Carbon county, Utah; (2) the erection of a large by-product coke-plant to produce the fuel for smelting iron ore; (3) the extension of the Sunnyside branch of the Denver & Rio Grande Western railroad to new coal beds that lie about four miles from the present terminal; (4) the opening and exploitation of rich iron-ore deposits in the Iron Springs district of Iron county, Utah; (5) the building of a 25-mile branch railroad to connect the iron mines with the main line of the Los Angeles & Salt Lake railroad at Lund; (6) the acquisition and enlargement of extensive quarries of limestone near Salt Lake City; (7) the construction, at the start, of a 500-ton iron blast-furnace near Utah lake,

25 miles south of Salt Lake City; and (8) the expansion of the existing steel plants of the Columbia Iron & Steel Company situated at Pittsburg, California, and at Portland, Oregon, and that of the Southern California Steel Company near Los Angeles. According to Mr. L. F. Rains, who represents the Utah interests in the negotiations, the States on the Pacific coast spend \$150,000,000 annually for iron and steel products that are brought, mostly by rail, from the steel-makers and sundry manufacturers in the Eastern States. The steel plants on the Coast hitherto have confined their operations for the most part to the re-melting of scrap-iron for making new steel, and the re-rolling of old steel into smaller shapes; necessarily, the output has been limited, and most of the finished products used on the Coast have come from the East. Utah is endowed by nature with immense deposits of all the raw materials required for the production of iron. In the property of the Utah Coke & Coal Company alone there is estimated to be available 75,000,000 tons of excellent coking-coal; it will produce a coke that meets both the principal requirements for blast-furnace operation, namely, structural strength to resist crushing by the charge, and low ash-content. The extent and richness of the iron-ore deposits were proved long ago, but heretofore conditions have not warranted the construction of a railroad and the opening of mines. An assured market for a reasonably large production of pig-iron is all that is required to justify the investment of the capital necessary to bring together the coke produced from Utah coal and the iron ore from Utah mines. An assured supply of pig-iron and an adequate market for steel products is all that is necessary to justify the owners of the steel plants on the Pacific coast in enlarging their plants and commencing to make steel in earnest. The advantages that may be derived from the proposed consolidation are obvious. In the final analysis the success of the entire project depends upon whether or not steel can be delivered to the consumer in the West at a price that will permit successful competition with steel from Eastern plants. It will be necessary to convince the capitalists who are considering the financing of the undertaking that this can be done, or they will not be willing to invest their money. An important factor in determining the unit cost of production is the scale of operations; obviously, the Western steel-maker will be at a disadvantage on this score. The fact should be emphasized, however, that the availability of low-priced steel from Western mills will result inevitably in the establishment in the West, instead of in the East, of plants for the manufacture of building materials, machinery, and other equipment for which raw steel is an important requisite. This will increase the demand for steel, it will permit the expansion of the scale of operations of the steel-maker, and will reduce his cost of production; in other words, the disadvantage arising from the restricted production at the outset will be decreased gradually, when once the Westerner's operations gain momentum. It is possible that some of the details as outlined above will be changed; it may even be that obstacles will arise to prevent a merger under any conditions of the interests

mentioned; however, the development of Western resources of iron and coal and the establishment of a steel industry on the Coast are assured, even though they be postponed temporarily. It is to be hoped that the present negotiations will prove successful. They will mean increased employment, expanded business, and greater prosperity.

Institutes and Technical Journals

In the November bulletin of the Canadian Institute of Mining and Metallurgy we find a long and labored editorial discussing our recent reference to the relation between that Institute and the 'Canadian Mining Journal'. As the writer in the bulletin suggests, we wrote not without sundry side-glances at New York, that is, we recognized the bearing of the discussion upon the relation between the American Institute and the technical press of the United States, more particularly the oldest mining paper on this continent, the 'Mining and Scientific Press'. Our Canadian critic acknowledges politely the compliment we tendered upon the general excellence of the Canadian Institute's monthly bulletin and then proceeds to analyze the contents of that publication. We are asked if we object to half of it being given to papers presented at meetings of the Institute. No, we do not; but we suggest that as the papers are printed in the bulletin, it would be well to save money by not re-publishing them in volume form at the end of the year. Why not bind the bulletins instead? The editorial comment in them is just as worthy of preservation as are the technical articles, and that is more than can be said for the editorials in the American Institute magazine. Next comes the current news of Canadian Institute affairs, which occupies a quarter of the reading matter in the bulletin. Again we have no fault to find; such news constitutes an essential part of the publication, of course. Then we are told that an eighth of the bulletin is devoted to a summary of news, and it is intimated that our animadversion is directed chiefly at this part of the publication. It is. The monthly publication of an engineering society has no business to trespass upon journalism, and the one in question would do so unsuccessfully if the 'Canadian Mining Journal' had not lost its prestige, largely because the bulletin is competing successfully against it, by aid of its subsidized status. We hasten to add, however, that the Canadian Institute sets an example to its American contemporary by charging a subscription of \$1 per annum to its members for the bulletin. That is worthy of imitation, because it is both fair and businesslike. Some people would rather be businesslike than fair, but most people are willing to combine the two, thereby salving both their pocket and their conscience. In the last paragraph our friend at Toronto—we assume that he lives in that lively city—changes from a spirit of urbanity and goodwill into one of irritation and aggressiveness. He wants to know whether we meant to "damn" the bulletin "in its entirety from cover to cover". My dear Sir, abate your impetuosity. We went out of our way, as you have acknowledged, to say kind, but true, things

about your bulletin; why then this petulant outbreak? However, we are always willing to answer a question, and as we are asked to state "in some future issue whether we [the gentleman at Toronto] are to read its [our] verdict in this sense", we say at once that we do think that the bulletin trespasses upon the function of journalism, which belongs to a technical paper—to wit, the 'Canadian Mining Journal'—and it does invade a field of activity not specified in its own constitution, as quoted in the article to which this is a reply.

Welded Pipe

The piping of natural gas to centres of population and industry is an evidence of a desire to utilize natural resources to the full and so to profit by the avoidance of waste. The practicability of laying considerable lengths of pipe, which will withstand high internal pressure, at a moderate cost has resulted from the wider adoption of the oxy-acetylene flame as a source of heat for welding. By employing an expert welder and with the aid of simple apparatus, it is now possible to construct, at comparatively low cost, a continuous pipe for the conveyance of gas or water. Mr. F. F. Doyle, one of the superintendents of the Midway Gas Company, describes, in a recent issue of the 'Mining and Oil Bulletin', the construction of 60 miles of 12-inch steel piping across southern California by this method, which would have a wider application were it better known. The following details may therefore be of interest to engineers engaged in other phases of the mining industry: The pipe used was of $\frac{1}{4}$ -inch steel, lap-welded, and tested to 600 pounds per square inch. The individual pieces averaged 21 feet in length, and were beveled at the ends to ensure a satisfactory joint. As the pipe had to be buried after construction, a ditch was cut, 22 inches wide and 3 feet deep, part by machine and part by hand. A 'skid-gang' consisting of a boss and eight men, worked ahead of the welders, placing skids across the ditch and laying the pipes in position. The welding crew consisted of a foreman and 16 welders, each of whom was given two helpers. Each welder was supplied with a complete outfit, including a carriage for the cylinders of oxygen and acetylene, and sufficient hose to obviate the constant moving of equipment. Each joint was marked, so that defective workmanship could be traced to its source. The results were satisfactory, for only 59 leaks were discovered out of 8695 welds; 48 of these were from pinholes that were subsequently repaired by caulking; only 11 joints had to be re-welded. The work took $4\frac{1}{2}$ months, an average of 1340 feet of line per shift being completed; each welder at the end of the day submitted a report as to the number of welds made, the amount of rod, acetylene, and oxygen used. The average was found to be 1.25 pounds of rod, 21.42 cubic feet of acetylene, and 23.6 cubic feet of oxygen per weld. Some of the welders were detailed to assemble sections of six or eight lengths of pipe; a 'tie-in' welder would follow who would join five of such sections; a second 'tie-in' welder would

finish the job. The junctions of the longest sections were always made in the early morning, when the pipe was cool and contracted. Eight ordinary welds, four to five angle-welds, or three 'tie-in' welds was considered a good day's work for one welder. The painting-and-lowering gang followed the welders; it consisted of a boss and 12 men. A primary coat of paint was first applied, allowed to stand for 24 hours, then covered by a coating of hot paint. The pipe was afterward lowered into the ditch by means of a tripod and chain-block; the ditch was then re-filled by means of a 'grader'. Motor-trucks were used to transport the men to and from a temporary camp, the framework for the buildings of which was fitted with plates and bolts, thus making it possible to move the camp a distance of from 10 to 12 miles in about six hours. Accommodation was provided for 130 men, the average number employed. The line is now in commission, under a pressure of 400 pounds per square inch; the work was thus brought to a satisfactory conclusion. There are many phases of mining and allied enterprises in which the use of a welded pipe would be practicable and where no disadvantage would arise from the need to dismantle at intervals. The strength of a pipe-line is at its weakest point; this is usually at a joint; a pipe of large diameter is often fitted with some type of packing joint, few of which are able to withstand continuous pressure without leakage. For obvious reasons the welded pipe will appear to have many advantages, particularly on account of saving in first cost.

Cyaniding at Virginia City

"Old-fashioned, but nevertheless the most satisfactory that we are able to devise." In words to this effect Mr. Walter L. Reid describes the treatment that will be used in the new 2500-ton cyanide plant that is now being erected by the United Comstock Mines Company at Virginia City. The company is a subsidiary of the Metals Exploration Company, which is headed by Mr. Bulkeley Wells; the enterprise consists of mining and milling at least 4,000,000 tons of low-grade ore and stope-filling from a number of old mines along the Comstock lode. The anticipated average tenor of the ore is four ounces of silver and one-tenth ounce of gold per ton, both metals being intimately associated with pyrite. Economical mining, made possible by block-caving and transportation through a new adit 9000 ft. long, is the first factor that is expected to make the enterprise profitable; the second is efficient metallurgy in a plant of large capacity now being erected near the portal of the adit. Mr. Reid, who is consulting metallurgist to the company, commenced his experimental work on the ore more than a year ago; although the design of the plant is now complete, some of the contracts for machinery have not been closed, and for that reason a specific flow-sheet is not available for publication. However, we are able, through the courtesy of Mr. Reid, to point out the interesting features of the treatment. Cyanidation of the raw ore entails the consumption of 3 pounds of cyanide and 18

pounds of lime per ton; for this reason in recent years the use of the cyanide process at Virginia City has not been accorded sufficient consideration in schemes for treating the ore. However, it was found that a large proportion of the deleterious constituents were soluble, and that a thorough wash with water would remove enough salts to reduce the consumption of cyanide to 0.8 pound, and of lime to 8 pounds per ton of ore. In the new plant the washing will be performed in rake-classifiers on material crushed to pass a $\frac{1}{4}$ -inch opening. The slime from the classifier will be thickened in a Dorr vat, and further dewatered in a vacuum drum-filter, the cake from which will join sundry other slime products that will undergo agitation with cyanide solution. The filtrate will be discarded. Three procedures were open for the treatment of the coarse product from the classifier: (1) fine-grinding and bulk-treatment of the whole; (2) fine-grinding and concentration, followed by separate treatment of the tailing and of the concentrate; or (3) concentration followed by leaching of the tailing and fine-grinding and separate treatment of the concentrate. The first permitted the simplest flow-sheet; the fashion of the day suggested the second; but experiment proved that the profit would be greater by following the third plan. In detail the practice will be to pass the $\frac{1}{4}$ -inch product with cyanide solution through a ball-mill for reduction to about 16-mesh; a rake-classifier *not* in closed circuit will remove any slime and leave a clean sand for concentrating. The tables will make four products: (a) concentrate, (b) middling, (c) sand-tailing, and (d) a virtually clear wash-solution. The last will be used to return the middling for re-grinding in the ball-mill; the sand-tailing will be leached, and the concentrate will be re-ground in a tube-mill in closed circuit with a concentrating-table, the concentrate or coarse product from which will be returned; the tailing or fine product will be given a continuous cyanide treatment in agitators alternating with thickeners. Slime from the final thickener will join the primary slime from the filter in the wash-water circuit for an additional treatment by agitation and thickening, the operation being concluded by final filtration in a vacuum drum-filter. There is nothing novel in the circulation and precipitation of the effluent leach-solutions, the overflow from the thickening-vats, and the pregnant filtrate from the vacuum-filter. Sundry special reagents will be used to stimulate and to accelerate the solution of the silver and gold in the concentrate, although no credit is claimed for having developed any mysterious or patentable process. The total cost for mining and milling is estimated at not more than \$2 per ton. The foundations for the plant are almost finished and it is hoped to be ready to operate by the middle of 1922. The new town that has already started to grow near the site of the mill will be called Comstock, thereby perpetuating the name of the famous lode, along a few miles of which 39 mines were in active operation at one time during the 'sixties, and from which more silver has been taken than from any other equal area in the United States. The success of the project will be another

triumph for the resourcefulness and the ingenuity of the mining and metallurgical engineers of our day.

The Boston-Washington Power Project

The North Atlantic coast region of the United States was selected some time ago for a study of the possibility of centralized power production because of the extensive requirements of industries and railroads in that area. The work was entrusted to the U. S. Geological Survey, with Mr. W. S. Murray, of New York, as chief of the engineering staff. A report is now published. The proposal involves the construction of large steam-power plants at tide-water or on rivers where condensing water is available, and hydro-electric plants in those districts in the zone, or within transmission distance of it, where water-power can be utilized. After 1930, cheap power from the proposed St. Lawrence project and from additional plants at Niagara Falls may be available for western New England and New York State—a region that will benefit greatly by the development of these new sources of energy.

A double economy is sought in the proposed scheme—in investment and in operation. The outstanding feature is the establishment of a network of intercommunicating transmission-lines, by which one system will be made to take the place of a great number of small units. It is estimated that 970 miles of 220,000-volt and about 5000 miles of 110,000-volt transmission-line will be required, which will involve an enormous consumption of copper. The 1200 miles of lines that are now in operation, at 33,000 volts and thereabout, will become distribution-lines for public utilities. This scheme of transmission involves an expenditure of \$104,000,000 by 1930; the total investment for the entire project up to that year has been estimated at \$1,109,564,000, of which \$693,218,000 would represent added capital, for existing steam-electric and hydro-electric plants valued at \$400,000,000 would be retained in service. The territory between Boston and Washington represents only 2% of the area of the United States, but contains about 22% of the total population. The region has been described as a crowded workshop; it contains 96,000 manufacturing establishments, 76,000 of which during 1919 used power in excess of 12½ billion kilowatt-hours; nearly three quarters of this was generated by the companies concerned, mostly in units of small capacity and operating at low efficiency, as compared with the standards maintained in the large central stations of the public-utility companies; it has been estimated that if the manufacturing establishments had been able to purchase power at standard rates, a saving of 13½ million tons of coal would have been effected. Assuming normal industrial growth till 1930, the complete electrification of the manufacturing and mining plants in the area would result in an annual saving of \$190,000,000 to the industries concerned, over and above the fixed charges involved by an investment of \$185,000,000 for motor equipment.

Railway electrification must be decided according to

density of traffic; consequently it would appear that, of the 36,000 miles of main, branch, and side lines in this area, only about 19,000 miles could be electrified with a prospect of ultimate profit. This would cost nearly \$500,000,000; but a saving of from 11 to 19% on the investment would result, or an average of 14%. Electrification is the solution of the problem of increased haulage at decreased cost; and in this connection it is interesting to note that an annual saving of about 9,000,000 tons of coal by the railroads would be accompanied by a considerable increase in the supply of available cars. No credit, in a material sense, is taken for the abolition of smoke, cinders, and noise, which would follow the substitution of electric for steam-locomotives, but the average citizen appreciates the absence of these nuisances, even if his pocketbook is not affected thereby.

The scheme outlined is so ambitious that it will appeal only to those who are convinced that the industrial development of the country will continue without abatement. As we pointed out in a recent issue, statisticians estimate that, without the use of modern machinery, several billion slaves would be needed to keep the wheels of industry turning at their accustomed speed, and irregularly at that; but, although machines may duplicate manual labor, manual labor could not do the work that many machines perform today, however many billions of slaves were put to the task. Our material development is in the right direction; it is tending to reduce the need for manual labor; by taking full advantage of the discoveries of this age of electricity we can compete successfully with the products of cheap foreign labor. Mr. Albert B. Fall, the Secretary of the Department of the Interior, in transmitting the super-power report to the President, said: "I believe the engineering facts and economic conclusions here presented will command the attention alike of the financiers, railroad executives, public-utility officials, industrial leaders, and others of that group of our citizens of large vision who are building for the America of tomorrow. Our present-day achievements have largely come as a result of our country's unparalleled wealth in raw materials; the larger use of our sources of energy must be planned with every effort to avoid waste. Had the super-power project outlined in this report been in operation in 1919 it is believed that 25,000,000 tons of coal could have been saved; and with the rapid growth expected in the coming decade, the saving possible in 1930 by the interconnected electrification of industries and railroads would be 50,000,000 tons. However, these economies on a truly national scale will affect not only coal but capital expenditure as well, and especially the output of human energy. Moreover, cheaper electricity must surely add to the comfort and prosperity of our citizens". In this we concur, adding that the utilization on an adequate scale of the products of our metal mines, for the construction of electrical equipment and transmission lines, indicates one of the best investments that can be made by a country which hopes to maintain the lead in civilized progress.

Mining Law Revision

The Editor:

Sir—I have read with interest the many discussions of the proposed new mining law that you have printed. Permit me to make a few comments, with two or three suggestions of amendments and additions which I think might well be incorporated into our present laws, in place of the proposed new law.

The nucleus of the present mining law in the United States originated in 1849 in California. From time to time similar local laws were enacted elsewhere throughout the country; these differed somewhat in details, but in all cases they were designed to meet existing conditions, in fairness to the prospector and locator. The present mining laws are thus the outgrowth and development of years of practical application. Various questions arising as to their interpretation have been settled in the State and Federal courts, so that the present laws are now well understood.

The Government is interested in having the mineral resources of the country discovered and developed; for this reason it is right that the laws should be favorable to the prospector and to the small operator, so as to encourage exploration and development. A prospector who finds a lode of pay-ore should be entitled to it, and so should be allowed to stake and locate the lode as it appears on the surface.

To make such radical changes of the mining laws as is proposed by the Arentz bill deserves the serious consideration of every mining man, senator, and representative.

Whether intentionally or not, the proposed bill unquestionably favors the large operator, and those interested in acquiring land, rather than those interested in finding and developing the mineral deposits. The Bill permits from 10 to 160 acres to be located and held up to 10 or 12 years without discovery and without requiring any development work. This will be detrimental to the development of the country's mineral deposits and will discourage the prospector who is earnestly in search of a discovery; it will cause mineral land, which otherwise might be opened up, to lie dormant and undeveloped. Furthermore, 160 acres is too large an area to be held by one discovery; there are places where this would cover the entire mineral deposit of a district, valued at many millions of dollars.

The proposed requirement that all mining claims must be patented within a period of seven years is unfair to the miner, who at present is able to keep up his assess-

ment work and so hold his claim, but who has not the available cash to patent his claim.

The purpose of the present law pertaining to extra-lateral rights is to guarantee to the locator his right to mine the ore from the deposit he has found, and so long as it is a continuation of his discovery it belongs to him; that is the theory upon which the law of extra-lateral rights was established. No one can logically question the fairness and justice of this law; it has stood the test of time; it has caused considerable litigation, but this is not sufficient justification for its abolition. In fact, there would still be considerable litigation between claims located under the old law and the new proposed law.

I believe that there ought to be an amendment or an

addition made to our present mining laws, allowing for the provisional location, protection, and holding of a claim, without discovery, so long as the holder diligently continues—by cut, shaft, tunnel, or drilling—the search for mineral upon his claim, and expends in labor and needed improvement the amount of \$100 per annum per claim; such provisional location not to exceed a period of 5 years.

The present law with respect to the position of the side-lines (R. S. Sec. 2320) states that, "No claim shall extend more than 300 ft. on each side of the middle of the vein, at the surface, . . ." I would have this read that, "No claim shall exceed more than 600 ft. in width, between parallel side-lines, the locator to state the distance from the middle of his vein, at the surface, to his respective side-lines". This would permit a locator to take, say, 400 ft. on one side of his vein and 200 ft. on the other, or any distance so long as the total width did not exceed 600 ft., and would do away with the present necessity of centring the claim with reference to the side-lines, which is an objectionable feature when laying out a group of claims involving a series of parallel veins.

Under the present law there may be a gap between some claims, and an overlapping of others, whereas the veins could be located by a continuous group if it was not necessary to place the side-lines 300 ft. on each side of the veins; see accompanying illustration. I would further recommend that there be an addition to the present laws, requiring that the boundary monuments of a claim shall be designated and identified by giving the respective corner and name of the claim; as "N. E. corner of — claim".

Relief for the Gold Miner

The Editor:

Sir—Being personally interested, as an owner of gold property, in all that pertains to the gold question, I have watched closely and have read carefully all the articles I could find on the subject.

It seems to me that all the writers are overlooking or neglecting very important points that should have full and intelligent thought. I have failed to see where any one has considered or mentioned the fact that, in view of the hope that conditions will get back to normal, but more in the hope that the McFadden Bill will be passed or that other legislation will again make operation possible, many low-grade properties have not been allowed to go to wreck, but, that, if their owners become discouraged in their hope and become convinced that no relief will come, those properties will be abandoned with further decrease in production of gold. These sustaining hopes have been the prospector's and miner's dream throughout depressing conditions.

I perceive that the present interest in gold mining is largely due to the belief or hope that the McFadden Bill will be passed; but the activity is only in the direction of being prepared and ready to reap the advantage when it comes; for, if legislation is to be only for temporary relief, as has been suggested, property owners would not lose any of the relief period in preparation.

I live in a little town that has its name and has had most of its support from the operation of a mine that has a record approaching fifteen million dollars in gold and molybdenum. That mine cannot be run at a profit under present costs and conditions; but even if it could, the owners would have no inducement to run. Why? There are two good reasons. First, the 65% above normal costs of production, would cover interest on the value of all the gold that could be mined during several years—that is the justification for waiting. Second, if legislation is to bring relief, the owners would not be justified in marketing their gold until that relief comes. The proposed bonus would cover interest and justify suspension for several years.

The legislation drags and the miner waits. Most of them are obliged to remain idle if their properties are of low grade. With a passing comment upon the declaration of Secretary Mellon, I submit my observations to be

treated as your judgment dictates. He says that there is at the present date in the United States more gold than at any other date in history, and large amounts are still coming. Possibly, but questionably, this may be true; but is there not more beef, bacon, butter, and beans, and more corn, cattle, cotton, and copper, more peas, pigs, pork, and pumpkins than at any other date? Why should there not be more gold, and still more be needed?

I have been in business and postmaster in this place for thirty years. During all that time, until the last few years, gold was the cash kept as money in the house, and miners had their cheeks changed into gold. During the last three years I have seen but three pieces of gold. Those were held as presents or keepsakes. Circulation and shipments of gold have been restricted, with the result that it has been piled up, and up, and up, and now when Mr. Mellon sees the pile, he says it is bigger than ever before. Very true. Why should it not be? I also challenge his argument that a bonus would prohibit the use of gold in the arts. Mr. Mellon is probably a judge of jewels and precious stones, but I venture the assertion that beauty of appearance would not satisfy him unless he knew the intrinsic value was behind the choice. It is the intrinsic value of gold that sustains its appreciation in the arts. An abasement of its value would decrease its use, but a doubled value would double its appreciation and greatly increase its use. Before silver was demonetized and debased, the family carriage and driving harness had silver or silvered trimmings, and during those days a house-robbery was generally described by stating that the family plate and silverware had been stolen. Who prizes such things now? If the price of gold could be placed at ten times its present value it would be that much more in demand in the arts and that much more appreciated by those who could afford it. To be exclusive and have what the common class cannot afford is one of the aims and joys of the rich, and of those who would feign the appearance of being rich.

Dry Grinding in a Model Ball-Mill

The Editor:

Sir—It was desired to crush one sample of slag so that 15% remained on 150-mesh (I. M. M.), and another sample of the same material so that 5% remained on 150-mesh. Only a small quantity of the material was available; each sample weighed 3 lb. Lot A was ground by means of 74 flint pebbles, which weighed 22½ lb., for 230 minutes in a model ball-mill; the product was then found to contain 13.2% on 150-mesh. Lot B was ground for 340 minutes under the same conditions and was then found to contain 12.8% on 150-mesh, thus showing no better grinding in spite of the extra time. The flints were then replaced by 74 steel balls weighing 66½ lb. and occupying approximately the same volume as did the flints. Grinding was continued on the same charge for 126 minutes, a sizing analysis of the product then show-

ing 19.8% on 150-mesh. The balls were removed and 45 lb. of flint pebbles was substituted; grinding was continued for 120 minutes. A sizing analysis then showed almost the same result as that obtained in the first test when 22½ lb. of flint pebbles was used.

It may be that, in dry grinding, powder below a certain size remains in suspension in the mill and so escapes further comminution. In this instance it was noticed that the steel balls were too heavy for the purpose; the effect was much the same as that resulting when a piece of toffee is struck with a hammer; small clots of the material stuck to the balls. The final attempt with 45 lb. of flints apparently merely rubbed down the clots that had been formed by the balls. Thus by using the model mill, which was 16 in. long by 26 in. diameter, at 43 r.p.m., I was unable to crush the material so that no more than 5% remained on a 150-mesh screen. Screening analyses were as follows:

		Product After Grinding			
		Lot A 230 min.	Lot B		
I	M M screen		340 min.	460 min.	586 min.
	On 60 mesh	0.8	1.1	2.0	1.0
	100	4.0	4.2	8.8	6.8
	150	8.4	7.5	9.0	7.0
	200	5.4	5.4	4.0	3.0
Through 200		81.4	81.8	76.2	82.2

Surficial Closing of Fissure Veins

The Editor:

Sir—Generally the idea of increasing richness and size of veins of gold and silver ores, with depth, is akin to the lure which the other side of the mountain or range holds for the old prospector. The writer has noted conditions in a few places which do sustain the hope of a bonanza with depth; they occur with a peculiar phenomenon which suggests the subject of this letter.

A Mexican was sent to examine an old mine in northern Sonora, at which an inch or two of tale in a little seam was the only thing which the original prospector found at the surface; he found four feet of sulphide ore at the bottom of a 100-ft. shaft. Closer examination revealed the fact that the soft tale continued some ten feet; a few little lumps of sulphide ore of silver, with iron and copper, then appeared. These nodules and bunches increased in size with depth and so did the width of the streak. Approaching the ground-water level the streak became one foot, then two feet in width at 75 ft., and the ribbon of ore in the centre became continuous. At the water, where the tale practically stopped, the heretofore broken and poorly defined walls became solid and uniform and the entire fissure was filled with good ore. This was at 100 feet.

Chancing to meet the prospector and asking him why he had sunk when he had neither quantity nor quality at the surface (it being usually considered that one must have at least one of these two elements to justify sinking on a prospect) he answered, simply, that he had prospected some years in the district and had learned that a

well-defined tale streak is all the showing at the surface, necessary to justify sinking, for such streaks almost invariably lead to ore.

The broken and loose condition of the rock at each side of the seam at last suggested a solution which is as follows: The country rock is siliceous, a quartz porphyry, and is less soluble than the original vein-filling which had gradually dissolved. As it dissolved, the walls did what the sides of a shaft or drift do when the timbers rot away—they yielded to the lateral pressure and began to close.

In the case of failing timber-support the result, generally, is catastrophe; but in the silent removal of the ore by water during centuries of almost imperceptible action, the walls, though cracking and disintegrating, slowly moved toward each other until separated by the small streak of tale, and in some instances they came entirely into contact and sealed the top of the vein.

Sometimes masses of country rock had moved for twenty feet or more on each side of the vein and the little fissures or gash veins they left behind them had filled with clay and calcite; as these substances did not serve to weld the broken masses to the rock from which they had been loosened, the walls of a shaft would not stand without timbering. There was probably a secondary enrichment of the ore in place for a distance, until well below permanent water-level where the impervious character of the firm sulphides, not accompanied with much downward movement of water in the vein, made unlikely any change in the original character or grade of the ore.

Had the country rock been able to withstand the side-pressure when the vein-filling dissolved and took all support away from that side of the wall, the probabilities are that a filling would have been eventually substituted for the quartz gangue and sulphides, disappearing with the sinking waters, and a ledge of barren spar might have greeted the prospector of the present day. A shallow pit would no doubt have convinced the prospector that the spar never was mineralized beyond a few iron and copper stains, and he would properly enough have discontinued the search for ore. A similar phenomenon has been observed in at least two other places.

Charcoal and Cyanidation

The Editor:

Sir—Your editorial on 'Charecoal and Cyanidation' reminds me that my father, the late A. Gordon French, experimented with and used charcoal for the precipitation of gold from cyanide solutions soon after the introduction of the MacArthur-Forrest process. As far as I can recollect, he was carrying out some investigations on cyaniding, in barrels that had previously contained oil. The oil had been removed by burning, which left a coating of charecoal in the interior of the barrel.

Knowing that charcoal was commonly used for removing the gold from solution in the chlorination process, he

was led to try if it had a similar effect with cyanide. He used charecoal for this purpose, between the years 1894 and 1900, in Australia and New Zealand at several small isolated mines where cyanide could be obtained, but where zinc shavings were not so readily available. But what is more interesting, he wrote to me, about the latter date, that the vats used in cyanidation absorbed the gold to a certain depth, and this again led him to try the effect of sawdust. I do not recollect whether or not he found sawdust to be more efficacious than charecoal, but in later years I often saw him demonstrate the efficiency with which certain kinds of sawdust removed the gold from cyanide solutions.

The McFadden Bill

The Editor:

Sir—In your editorial of October 22, referring to your interrogatory concerning the present condition of the metal-mining industry, you made some comment on the McFadden Bill which seems open to discussion. I refer particularly to the following:

"If any special legislation favoring gold mining is likely to be passed, it will be welcomed by those whom it will help, but many of them are honest enough to recognize the improbability, and even the impropriety, of such legislation, and are content to have the free market for gold maintained without prejudice."

Where an injustice has been done to an individual, a group of individuals, or an industry, even though done unwittingly, it should be corrected if possible. In 1915, the United States produced gold valued at \$101,035,000, of which \$37,820,000, or 37%, was used in the arts and manufactures. In 1920, the United States produced \$49,509,000 in gold, while the arts and manufactures used \$75,490,000, or 50% more gold than was produced in the whole country. To get this gold, they went to the mint and paid \$20.67 per ounce for it, the same as they paid in 1915. In the meantime, the cost of producing gold and delivering it to the mint had risen enormously. The users of gold in the arts and manufactures had no limit placed on them by the Government in fixing the selling price of their manufactured articles, and they were consequently enabled to reap handsome profits at the expense of the producer. The latter was, in effect, penalized for producing gold during a period of high prices.

It is true that a premium on new gold may not be required to maintain the gold-reserve of the country and the McFadden Bill cannot be entirely justified on this ground. The gold reserve of the country is being increased solely by the favorable trade position of the United States, it being the chief creditor nation of the world. Instead of using any of our 1920 gold production to add to the gold-reserve, there was in fact nearly \$26,000,000 drawn from our reserve to supply the arts. If an actual "free market for gold is maintained with-

out prejudice", is it to be supposed that manufacturers, under conditions existing since 1915, could obtain their gold at \$20.67 per ounce, a price fixed by law when the general average price of labor and materials was supposed to be normal?

England has recognized the situation by the payment of a premium to South African producers, and to a large extent as a result of this premium, South African production in 1920 showed a far smaller percentage of decrease than did that of the United States.

The War Minerals Relief Act compensated producers of tungsten, manganese, chrome, etc., for their losses; why the impropriety of compensating the gold producers? Gold producers were urged to keep up their output and their employees were classed among the essential industries. It seems to be evading the question and not facing it to say that the difficulties facing the gold producers will gradually adjust themselves without government aid as deflation progresses and commodity prices return toward normal.

It would appear that the injustice done the gold-mining industry can, in a measure, be corrected by the passage of the McFadden Bill, and that Senator Oddie deserves full support in his attempt to convince the Secretary of the Treasury of this fact.

S. J. KIDDER.

Mogollon, New Mexico, November 3.

Taxing Gold Producers

The Editor:

Sir—In the questionnaire that you have addressed to mining engineers an important query has been omitted: Do you think it reasonable that mining corporations should be bulked with other corporations for taxation purposes?

The opposition to the McFadden bill seems to spring from the conviction that it is economically unsound to single out any particular industry for special treatment. The obverse of the argument is overlooked, that the gold-mining industry is the only one that is so singled out at present, in that its product is legally removed from the operation of the law of supply and demand and its price fixed regardless of the cost of production.

The yearly shrinkage in our gold yield should surely show our sapient legislators that some encouragement is needed if the industry is to survive. Why not put a flat rate of income tax of, say, 5% on profit over 5% on the capital invested in gold mining, whether it be a partnership or an incorporation? At present a company has to pay a Federal tax, a State tax, and a county tax. The last-mentioned, being levied on the capital value of land and plant, is often the most onerous of all. In addition to all these burdens a 15% corporation tax is to be imposed, just to encourage people to keep their money out of gold stocks, to please the faddists, and to drive one more legal nail into the coffin of the enterprise.

Rogue River, Oregon, October 29.

The Comstock Lode in the 'Sixties

By R. H. Stretch

When recently at Virginia City, Nevada, the editor of the 'Mining and Scientific Press' happened to see some of the maps of the underground workings on the Comstock Lode, made by me, and thereupon suggested in a recent issue that I put on paper some recollections of those early days. Hence this article.

Born in 1837, I unluckily began life too early—too early for this modern life—and the summer day in '63 on which I walked into the office of L. E. James at Virginia City and became his partner in less than an hour, though we had never seen each other previously, was the date on which I first went to school to learn something of the art of mining. My ability to do good 'lettering' gave me this opportunity. I had never handled a transit; I had never been in a mine; I had never seen metallic ores except as curiosities on the shelves of a museum, or gold, except as a coin and a rarity at that; but nobody was aware of the fact, because nobody asked me about it, in true Western fashion, and I soon discovered that I was not so badly handicapped as I feared. It was a strange community that foregathered on the slopes of Mt. Davidson, 6000 ft. in the air, with 40 miles of desert spread out before us, where life seemed to be limited to the 'dust-devils' that danced and envetted to each other in the blazing sunshine. There certainly was nothing to distract our attention from the main industry of litigation! I had dropped into a community, professedly a mining one, but one in which the product of the mines went into the pockets of a brilliant group of lawyers, or into those of surveyors, experts, witnesses, and hangers-on, while the stockholders lived on the diminished dividends or on the fluctuations of the stock market. It was generally supposed that every attorney in town who was not engaged to fight for a proposition was paid to keep his mouth shut. It soon became apparent, however, that knowledge acquired by burning the midnight candle into the small hours of the morning, might have a cash value though acquired at the cost of a damaged reputation; for in England in the '50s the individual who dared to even whisper that the world was more than 6000 years old, that all things were not made for Man, but that he was largely the result of his environment, and that the mysterious objects found in the rocks were not special creations, but the remains of animals that had lived and died thousands or even millions of years before the advent of Adam, was likely to be branded as an atheist!

In the '60s things were better. The natural sciences had gained a secure foothold, but deep mining, especially for the metals, as we now know it, was in its infancy in America. A start had been made in California, for the outcrops of the veins on the Mother Lode were so bold and easily traceable that no serious or puzzling geological problems had been encountered to call for legal aid in

their solution. There were no National or State laws governing the location of mining claims. When a new district was discovered the miners made their own law to regulate the length of the claims and their lateral limits; it was usually a declaration that no parallel location could be made nearer than a given number of feet from the one already located. What this distance was on the Comstock I am unable to recall, but it was probably more than the 50 ft. in the camp of Aurora, some miles to the southward. The result of this custom in a region four miles long, striped with innumerable mineral stains and outcrops for more than a thousand feet east of the intermittent white quartz outcrops on what appeared to be the western limit of mineralization, can be easily imagined. When it was learned that the black sludge in the sluice-boxes of the miners at the north end of the district was worth thousands of dollars per ton, a wild era of staking followed. Every mineral stain showed a location notice, so that when I wrote the story of the Comstock at the request of Ross Browne, for the Government in the first issue of the 'Mineral Resources of the West', I found, in reply to one of the questions asked, 39 mines in active operation and more than 5000 locations on record in the Virginia City, Gold Hill, Silver City, and American Flat districts! No wonder that when the 'one-ledge' theory was proved correct there were hundreds of suits on file that died sudden deaths. The present 'apex' troubles are as nothing compared with ours, for it soon became apparent that the bonanzas were few and far between, and that there was no clean-cut fissure on which they were strung as beads on a cord; there was no conception of the unity of the lode as a single geological problem, and every showing of value was soon attacked by a swarm of claimants to a share of its visible or potential millions.

It is no wonder that the situation attracted the best brains of the legal fraternity on the Coast, among whom Judges Quint and Mesiek were prominent attorneys for the 'many-ledge' plaintiffs, with William M. Stewart (familiarily known as 'Bill') and Curt Hillyer for the defendants, aided by such men as Garber, Thornton, Ellis, Huntington, Judge Baldwin, and others who later maintained their reputation in other arenas. Trained experts arrived sporadically, for there were few in the country at that date, and it seems a sad commentary on the importance of the presiding judges that I am unable to recall their names, while the scenes and personalities below the bench are as vivid as in the days when they were enacted. Judge Goodwin gave us a first-class newspaper in the 'Territorial Enterprise', on which Mark Twain was then a reporter and spent many hours in our office to get a glimpse of my partner's wife, whom he had hoped to make Mrs. Clemens; another well-known char-

acter was Adolph Sutro of tunnel fame, for whom I made a relief model of the country around Virginia City, covering a square six miles on a scale of four feet to the mile; but as in the case of the Latrobe tunnel, run to explore the west outcrop on the Andes location, the workings had reached below the level of his tunnel before it was completed, and complications arose that led him to choose the opposite side of the street when we met, as in the old-time story, for he had come to look on us as his natural enemies. Our bread was not buttered on the same side.

The only visitor of prominence from the outside was Baron Riechthofen, who was on his way to China to examine its mineral resources for the Prussian government. His visit was very short, and the only memento of it was the word *propylite*, which he applied to the altered andesite of the East country at Virginia City.

Among the mining superintendents, I recall Sam Jones (afterward U. S. Senator) of Gold Hill, H. Yerrington of the Kentuck (later of the V. C. & T. R. R.), Isaac Requa of the Chollar-Potosi, Charles Bonner (later of North Bloomfield), and Louis Janin of the Gould & Curry; Pat McKay of the California, and James (Jim) Fair, and Buckminster of the Ophir. I can visualize several others, but cannot name or place them. How little the geologic problems interested these men can be judged from the fact that only Mr. McKay used to come to the office to discuss questions of cause and effect. To the others the discovery of a new clay seam, increasing the complications, was more important than the causes which made it, as the many-ledge theory held that even if it cut an orebody in two it made the orebody two lodes. But of this more anon!

We were a community of some 25,000 souls on the outskirts of civilization, connected with it by telegraph, but separated by 190 miles of mountain stage-road known as the Kingsbury grade, even if it was a first-class piece of construction for those times. It was kept in splendid condition, sprinkled daily to lay the dust, and all freight teams were compelled to park at nightfall in suitable places that the three Concord coaches leaving each afternoon could make the trip to the railroad at Placerville on a schedule of ten miles an hour. Some staging! Each stage was well ballasted with heavy bars of bullion, except on the memorable ride of Horace Greeley, who, traveling light, was tossed about like a grain of corn in a popper, while his plea for less action only elicited from the driver, "Keep your seat Horace, we'll get you there on time", if Mark Twain's veracity remains unquestioned; which reminds me of Twain's lecture on the Sandwich islands after his return from Honolulu—not one word about the islands but the Greeley story with infinite variations, and the audience in a continuous roar of laughter.

We were an orderly self-contained community. The 27 in the cemetery, who had died with their boots on, slept peacefully. Tom Peasly, the last of the gunmen, who killed his opponent in a Carson City bar-room after being shot through the heart, begged the boys to get his

boots off and they succeeded. We were no longer disappointed if we did not have a man for breakfast! Differences of opinion were occasionally settled in an unamiable way, as when Frank Farrington and his opponent tried to pot each other from the shelter of two telegraph posts on C street and I had to seek shelter from the unprofessional shooting. The attitude of the miners was strictly for law and order, and their number enforced obedience. No big body of men were ever better paid. Four dollars a day in gold for eight hours, when currency was worth about 40 cents, made them the best dressed body of workmen, when off duty, to be found anywhere. Saloons there were, and splendid ones, but their chief ornaments were valuable mineral collections, to which the men were proud to contribute (one of these belonging to Ed. Powers was exhibited in later years at the Horse-shoe saloon in Seattle); the chief subjects of conversation were rumors of new strikes and the fluctuations of the stock market, in which, to the last man, all were interested. I recall but one regrettable case of sabotage, and that was the burning of the Melodeon, as the vaudeville theatre was called, under the mistaken impression that it was the property of Mr. Bonner, who had been instructed by the directors of the Gould & Curry mine to reduce wages to three dollars. When a large body of men appeared at the office, Mr. Bonner slipped out of the back door and quit the city, as recorded in the following doggerel, which was a roaring success at the Melodeon for a short run:

"Mr. Bonner, the son of a gun
From Virginia City he had to run.
If we'd 'a got him, before he got away
He'd never 'a seen three dollars a day!"

It seems certain, however, that the fire was accidental or an act of private revenge, as the miners were active in fighting the conflagration.

This attitude was also of vast importance in maintaining order during the exciting times in the autumn of '64 and the presidential election. The city has a hotbed of secession. No small number of our citizens had drifted across the plains to escape the draft, some were deserters from both armies, and others were refugees from the war-devastated States on the fighting border. Their sentiments were well known to me, for I came into close contact with them while driving a four-horse team from Illinois to the Far West in '63. In September the Democrats carried the local election, but, thanks to an aggressive fight, the Republicans turned the tables by a good majority in November. If a man became too blatantly 'seecesh' the Provost-Marshal was sure to land him in the pen, where the salt-train camels, in a near-by corral, made both night and day hideous with their perpetual groaning. I had to demonstrate to the foreign-born element that the Democratic party of those days was the representative of aristocracy in Europe, and I have never found cause to regret that, being without a vote, I paid \$16 for four poll-taxes and voted my four men as a patriotic contribution. The night before election we had a parade with 2400 torches in line, for which

I painted many of the transparencies, and swept the town to the song of

"What's the cause of all the row?
What, what's the matter?
Doc. McMeans and all his crew
Cannot put secession through!
That's what's the matter!"

Next morning the whole city talked in whispers—we were like a lot of malamute dogs—decidedly 'husky', but we helped to win the fight, as the gold we were mining helped to save the Nation! When the result was known, the Silver Cityites, who laid down a Confederate flag in front of the polling-booth, sent a big covered wagon to Virginia City filled with mourners mopping their eyes with huge bandanas. The horses were draped in mourning; four reversed brooms bound with black crape ornamented its four corners and a huge triangle heralded its coming with a doleful dong! dong! The procession was a pronounced success, until it reached Gold Hill on its return journey, where it was ambushed by the Brown Rangers and met an ignominious fate! Thenceforward the staple excitements were stock-gambling and litigation.

The orgy of stock-gambling was beyond belief, but the tale has been told by better pens, so let it pass. Bret Harte's story of the Devil and the stock-broker was admirable. The Devil fishing for souls from the parapet of a church in San Francisco was only moderately successful, but finally caught a stock-broker. The broker, smarting under the rough treatment he had received, bet His Majesty that he could beat him at fishing, and Satan, knowing that he had the broker anyhow, took the bet and an afternoon stroll down the street, leaving his tackle with the broker. The broker was in his element, landing the poor fools so easily that when, after a terrific struggle he landed the Devil himself, the latter confessed his inferiority and asked what bait had brought such success. The broker whispered in his ear "wild-eat"!

It was not long after taking my seat at the drafting-table before it became apparent that a comprehensive map of all the workings on the Lode, on a continuous sheet, would be of great value in working out the difficult problems that faced us. Through the courtesy of Marlette & Hunt and Mason & Ostrom, both firms of surveyors, I was able to make such a map on a scale of 100 ft. to the inch, which showed fully 90% of the developments at that date, and this map was religiously posted up monthly as long as I was at Virginia City. This was again posted up for the survey of Clarence King, and again, at a later date for George F. Becker, so that the result of this work (which took five months) when published showed over 250 miles of underground workings, including drifts, shafts, and winzes. The squares on the key-map were based on the magnetic meridian, as the general trend of the Lode was magnetic north and south, and gave the foreman an easy method of determining the direction and distance to be run to reach any objective. The system of squares also gave us the means of outwitting the 'wire-tappers', who were

learning the developments as quickly as the mine-offices at San Francisco. By lettering the squares 1, 2, 3, etc., and A, B, C., etc., we were able to code our messages and easily change the code by altering the arrangement.

Improvement of the maps for use before a jury was the next thing. Ross Browne humorously declared that a mine-map looked more like a bunch of varicolored spillikens than anything else, and he was not far wrong, for on many of the early maps there did not seem to be any unified scheme of workings, and they must have been absolutely unintelligible to the average jurymen, who does not usually possess the ability to make a mental picture, giving to each part of the map its true position in space with regard to all others, as they appear in a model—a refinement then unknown to us. We did, however, simplify the exhibits by adding to them separate tracings of each level, the whole series being correctly superimposed and clamped together, so that each sheet could be discussed individually; then, by turning over the sheet we could descend to the next level, and so on, while in each case the succeeding level in depth could be faintly seen through the semi-transparent cloth. The main shaft held the same position with regard to the margins of all the sheets, and to make it easy to correlate the depth of the workings of the different companies involved, the depth below the outcrop of the Eldorado location (the highest on the lode) was added in brackets to each level shown on the map.

The instrumental work underground was no child's play, especially when great accuracy was demanded, as in spotting a raise to meet a shaft, or a winze from an upper level. Time was deemed so valuable that the hours necessary to project the surface base-line to each level as it was opened were begrudged as dead waste, while the variation of the needle was necessarily very erratic in the drifts. Our worst enemy, however, was the instability of the ground, especially in the vicinity of the big blue-clay seams, which, when exposed to the air began to swell with inconceivable force, disturbing all reference-points in the neighborhood. It was necessary to replace the timber ten or twelve times to keep a short drift open during the trial of the Burning Moscow v. Ophir case, and when finally abandoned it was completely closed in a few weeks. In some stopes the ore was so completely crushed as to be known as 'sugar-quartz'. In the Bullion mine slabs of quartz had been polished to a lapidary's finish. By the time the 700-ft. level was reached the old shafts were out of plumb, and had to be abandoned. On the last day that the old Savage shaft was in operation the cage stuck at 550 ft., and 150 ft. of hemp rope coiled up on the hood. When the engineer hoisted without being notified, the cage shot up when the strain pulled it loose and I spent half a minute on its floor in pitch darkness. Did I think of all my sins—not much! at the 500 I got my bearings, at the 200 I was on my feet and safe, unless the transit legs should break and make trouble. When I went home without a transit (smashed by icicles at the Yellow

Jacket ISO, and a rotten rope had sent an avalanche upon us in the Eldorado incline, and I had spent four hours in the abandoned stopes of the Seneca in black darkness without a dry match, there was no more peace in the family circle. No mining geologist should get married! He is too much away from home and runs too many risks for marital comfort!

Even in those early days we began to feel the steady increase of temperature by causing unequal expansion in the transit, but not until several years after my time did the high temperatures call for three relays on a shift and seriously increase the cost of mining. Digressing for a moment, it may be said that at the date of Professor Becker's survey, the cooling-room was 100°F. and the workings anything from that to 140°. As he could not stand the heat for any lengthened period, I made him a mask, covering the mouth and nose, to which was attached a gauze-wire cup filled with ice through which he had to breathe. In the '90s, during my last days underground with Emmet Boyle, clothes were useless, our note-books were thin boards, and pencils a solid piece of black chalk, for the glue melted out of an ordinary pencil and a paper book became a lump of saturated rag in a few minutes.

It is useless to go into the details of how we passed from the plank-lined shaft to the modern crib, from the bucket to the guide-controlled skip, hoodless at first; from a rag tell-tale on the cable to a clock-faced indicator; from dependence on the brake to direct hoisting; and saved re-handling of the load in a shaft, which changed from the vertical to an incline, as at the Crown Point & Belcher, by instituting the 'giraffe', which carried the car up the incline on a level platform, so that it could be run directly onto the cage.

The reduction of the ore to bullion, however, cannot be passed by in silence. There were no concentrators or classifiers between the battery and the amalgamating units. The millmen fell back on modifications of the old Mexican 'patio' methods, grinding and amalgamating the crushed ore in large Wheeler pans, with the addition of salt and bluestone, and settling the pulp in agitators, from which the waste water and slime passed over the rim. The average extraction was about 65%, and if this amount or over was returned to the custom-mills, no questions were asked. Grab-sampling was the universal custom. Few mines owned their own mills. Under these conditions it is not surprising that the position of weigher at the mines was a most desirable means of making a living. Some of the mills made an effort to impound their tailings for future treatment when oxidized, but the vast bulk went to waste in Six-mile and Gold canyons, to the amount of something like \$100,000,000! Recognizing this waste, which was rich in quicksilver, Billy Welch of the Gould & Curry mine, whose mill was on Six-mile canyon, and myself, prospected the canyon. We found many little pockets of mercury in the pot holes, but too scattered to pay for collection, and traced some of it down to Carson lake, but found no bodies workable with such appliances as

were then in existence, and badly mixed with vegetal matter.

Nearly all the mills were situated in the valley of the Carson river as far as Dayton, or else in the Washoe valley due west of Mt. Davidson, the wagon-haul ranging from 12 to 25 miles, at an average cost of \$5 per ton; and long were the teams and huge were the loads that daily swept through the Devil's Gate at the south end of Silver City. Timbers were brought from the Sierra Nevadas on a heavy up-grade of 12 miles, and later on from the end of the V-flume at Carson City when these eastern slopes had been denuded. Fire-wood from the same source cost \$14 per cord and later rose to \$16. In one memorable year, when three feet of snow fell overnight in the latter part of April, the price went up to \$40, and the Chinamen made fortunes out of the roots they had dug from the deforested mountain.

Under these conditions the cost of mining and milling was about \$16 per ton, and by the end of 1866 ore that would average this figure was becoming a scarce article in the stopes. No new discoveries were being made, and a reduction in the cost of transportation and supplies by building a railroad seemed the only salvation of the district. Mr. James had already examined the northern route through Long valley to the Truckee river, down which the Central Pacific proposed to build, so with him at the transit and myself at the level, we worked south and located a feasible route by way of Carson City and the Washoe valley to the present site of Reno. A detailed statement of the then actual traffic between the termini, and a careful estimate of the cost of construction and equipment showed that a reduction of 50% in freight-charges would still leave a fair margin of profit. As a matter of fact, the cost of the road, with a slight change in the route, was close to the estimate of some \$2,000,000, and paid for itself in two years. It was hoped that the principal mining companies would assist in financing the enterprise, but they stood aloof on the ground that such obligations might depress the stock market; but, after much dickering, a scheme was worked out which satisfied the parties who were furnishing the bulk of the capital, and the necessary signatures of the presidents of the contracting mining companies (save only one) had been secured, when the stock market went to smash and the project fell through. Shortly afterward, however, Sharon and Mills secured a new charter; James was notified while eating his Thanksgiving dinner in 1868 to take the field, and the line was opened in exactly one year to a day. During the bonanza days of the '70s the traffic rose to more than 40 trains daily each way, for a cubic foot of timber went into the C. & C. stopes for every cubic foot of ore extracted, so thoroughly had the orebody been crushed.

This collapse of the stock market killed a countless number of wild-cats, and potential millionaires became real beggars overnight. Moreover, the one-ledge theory had won its fight, and money was so scarce among the many-ledge claimants that the armed posse who had held the stopes of the Bajazet & Golden Era against all com-

ers, were glad to accept their per diem wages on a basis of 24 hours to the day! The end of litigation came suddenly. During its pendency neither side had been able to prove its theory. The one-ledge men had not been able to prove that the veins east of those on which they were working united in depth, although it seemed probable; neither had the many-ledge advocates proved that they could not, so that it is no wonder that the juries of non-scientists never agreed, and I do not recall a verdict for damages or possession. When the suit of the Bajazet came to trial there was still want of proof, but we presented a cross-section showing a probable connection at no great depth below the actual workings. The Court promptly ruled that it was not suitable evidence and ordered it withdrawn, and the ground that is contained speculative and unproved matter to influence the jury. As a matter of course the jury failed to agree. On re-trial we offered the identical cross-section map without change of a single line or letter, as the then state of exploration. The case was complete; the unity of the numerous parallel outcrops was accepted as a fact; the legal fraternity drifted away to other more lucrative fields and the community settled down to the actual business of mining.

As might have been expected, there were many laughable incidents to mitigate the dreary proceedings in court, and many of the practical miners came to grief. One of these whose testimony had to be smashed, stood up well under cross-examination until the lawyer worked back again, from the domain of quartz in the mineral and vegetal worlds to the inevitable clay seams, when the following colloquy took place: "Captain, you testified there was a clay seam in the west cross-cut?" "Yes, Sir." "And it dipped 60°?" "Yes, Sir." "Was that from the horizontal or vertical?" "From the vertical." "Captain [as if the questioner were in doubt], how many degrees are there in a circle?" "Ninety." "Did you never see a circle with more than ninety degrees?" "There might be if it was a very large one" [with a sigh of relief]. "You may step down, Captain."

As before stated, we had few trained professional experts, for the schools had not then trained such persons to any noticeable extent, but the troubles of one, who has long since ceased to worry about mundane affairs, come back to me vividly. He had been a witness for the one-ledge theory, and on re-trial of the case was found among the talent for the other side. Curt Hillyer piteously made him eat his first testimony from beginning to end, page by page, and when the Professor said, "I would like to explain," he replied, "You shall have all the time you wish when I get through". At the close of the cross-examination, when asked why he changed his opinions, the answer was, "On later developments." "Please state where they are"—an impossibility, as none had been made. The final question, "Now is it not a fact, Professor, that you are receiving a larger fee in this case than in the former?" No answer. It was tragic. The Professor's hobby was conchology, and there must have been something about his

personality that induced the boys to make fun of him. At any rate most 'ologists at that date and many years later were thought by many people to be a little 'off', you know, and fit subjects for practical jokes. As an entomologist I have had my share, and have retaliated by making the hobby a camouflage to the real object of my presence in several Californian camps when secrecy was advisable.

What possessed my partner I do not know, but with the help of two miners, sworn to secrecy, they cut a clean seam in a drift not often used, where a healthy clay seam would be of considerable value to the contention of the other side, and carefully filled it with the well-known blue clay of the Lode. Following this we held a subdued conversation near the attorneys to the effect that it was strange they did not know of this seam, the result being that when the Court adjourned at noon, they asked for a recess of two hours to investigate some new evidence just called to their attention. A delegation from both sides went underground and sure enough there was the evidence so greatly desired, until somebody picking into it, as men naturally will, unearthed an oyster-shell! When the Court met, the attorneys explained that they had been mistaken, and the judge, who had been posted, ordered the case to proceed, but failed to suppress a faint smile. Costs: a bottle of champagne.

All cases were tried before juries. It was easier to influence the judgment of one man out of twelve than the judge on the bench, as proved by the fact that the probable verdict was usually, if not always, known by some outsider before it was rendered, in spite of the precautions to prevent leakage. The jury when once empaneled were never allowed to go home or even see their wives without a deputy sheriff being present. They were guarded by a cordon of deputies, and these in turn by men employed by the litigants; and when a case lasted a fortnight it is not difficult to realize that their judgment might be biased against those who had got them into the hole. For instance, our next-door neighbor was drawn for duty the day he returned from his honeymoon, and for two weeks never had a moment alone with his wife, who was an entire stranger to the town, and disconsolately walked the sidewalks in front of the office, hour after hour!

For reasons unknown, I was appointed State Mineralogist in the winter of '65-'66 and owing to the general sentiment about 'ologists, the office very nearly became honorary, as the next legislature attempted to divert the funds from which the salary was to be paid. This incident illustrates the light esteem in which science was then held by the masses (or "them asses" as the 'Argonaut' called them). The office desired to secure a valuable collection of the State's mineral resources for the Grand Exposition at Paris, but though hundreds of circulars were sent out asking contributions, to be carried free by stage or express, the replies were so pitifully small that I sent my private collection of some 700 specimens along with them, and never got it back. In a similar way, the annual report, of which the legislature doubled the num-

ber of any other, found small favor among operators, as the closing chapters called attention to the necessity of curbing wild-cat schemes, the folly of building mills before the mines were developed (some of them never dropped a stamp), or of attempting the reduction of complex ores by the same methods used on the simple combinations of the Comstock. No one denied the facts, but an abundance of abusive letters reached the breakfast-table and spoiled my wife's appetite. Conditions have changed so little that it would be pertinent reading today.

In 1866, Aurora or Bodie was our nearest mining neighbor to the south, with Humboldt and Austin to the east, but all of them were from 100 to 200 miles away. Slowly a few other camps got a foothold, but Nevada is inhospitable to the prospector. Rivers and lakes are few, and much of it is desert. Up to 1866 the southern portion was an unknown Sahara, traversed only by the Butterfield stage-route, which passed through Las Vegas (the meadows). Dave Buell, an intrepid explorer, had been compelled to turn back for want of water; Stockbridge had gone into the desert and never returned; Judge Ralston had perished miserably chasing the desert mirage; and Breyfogle had turned up at Las Vegas, ragged, wounded, and deranged, but with splendid specimens of gold ore. Stories of rich strikes at Pahrnagat in southern Utah reached Virginia City by roundabout ways, and a bee took lodging in the brain of Governor Blaisdell. Election was approaching and it would be a great feather in his cap if he could pioneer a route across the wilderness and bring the trade of the new districts to Nevada's western towns.

So the expedition was organized, if inviting oneself can be so called. Each man furnished his own outfit, which ranged from that of an old campaigner like myself, and chum, to a one-horse wagon that carried a big cooking-stove and two men. The Governor had a buggy with two horses and three pack-mules loaded with barley, and was accompanied by a corporal's guard from an Army post to take care of the Indians. The episode was serio-comic. Among the company we had perfect specimens of Faith, Hope, and Charity, Optimism, Pessimism, True Grit, Indomitable Preservance, Selfish Laziness, Foolhardiness, and Caution. But that is another story. Disintegration soon started, and by the time we reached Silver Peak the guard returned home; the Secretary of State had important business at Carson; the Governor would have gladly quit, but was ashamed to do so, and, if I remember rightly, only 12 to 15 went into the desert and were lost to their friends for three months, emerging minus one man and several horses, after nearly a thousand miles of wandering, including the many times we had to take the back track for want of water, or die. We made no discoveries, but we left a wagon-track from water-hole to water-hole, and I was able to fill out the map of southern Nevada, till then a blank; while during the autumn several new camps were located on our trail.

When looking back, all the incidents of these years seem trivial. There were no spectacular incidents. We

were an orderly community, playing with a vast complicated toy; proud of our success when a few pieces fell into their true places; never disheartened by failure, and willing to pass on to others the task of relegating the remaining fragments to their true places. Others have followed who were more fortunate in their early education. I can recall only one name (Louis Janin) that became a household word in the long list of world-known mining engineers, but at the end it is pleasant to subscribe to the sentiments of a poet whose verses appeared in the 'Atlantie Monthly' for 1860:

"And when foot-weary with the day
My longing spirit only feels
The tremor of the chariot wheels
That bears some victor on his way.
I'll deem it very kindly chance
That gives the apprehension clear,
To feel the pageant far or near
That moves to other's utterance."

DR. A. L. MEYER has devised a method for determining the amount of fine dust particles in the air, which is based on the principle that water when brought into intimate contact with air removes the insoluble particles that are in suspension, states the 'Journal of Industrial Hygiene'. Dr. Meyer employs a graduated syringe which enables him to measure the quantities of air and water used and in which thorough contact is effected by shaking the two phases. The number of particles taken up by water is estimated microscopically with the aid of oblique illumination and Levy's blood-counter. The average deviation of the number of particles per cubic centimetre of air containing 20,000 to 80,000 particles obtained by this method was not more than ± 4000 for 100 cc. and ± 2000 for 200 cc. samples. The method is specially suitable for the determination of smoke particles in the atmosphere and for testing the efficiency of air-filtering devices in various ventilation schemes. As a comparison is not made with figures obtained by other methods, it is impossible to assess the accuracy of the method, which has also the drawback of not estimating the water-soluble particles.

ALTHOUGH large deposits of iron ore and phosphates are known to exist in Cambodia, alluvial gold in Laos, and zine, lead, antimony, and tin in Tonking and the Annamese hills, little exploitation has been done in French Indo-China, according to a British consular report. Coal is raised at Hongai, Dong-trio, and Phamme, all in Tongking. Zine is worked at Cho-Dion and Trang-Du (Tongking); the output was 48,000 tons in 1916, but decreased subsequently. Tin and wolfram occur chiefly near Langson in west Tonking and at Hinbun on the Annam-Siam frontier; the production in 1918 was 604 tons. Graphite, antimony, lead, and iron are found near Haifong, where a smelting furnace has been in operation since 1919. The chief causes of the decline of mining in Indo-China are high wages, working costs, and freights, the state of the metal market, and competition from other countries.

The Motor-Truck in Mining

By F. W. Fenn

*All industry has been passing through a period of readjustment. The years of the War, with their extraordinary demands, are behind us. Yesterday the object was production at any cost; today every mining engineer and executive realizes that he must obtain the minimum cost. This is especially true of concerns that are still paying high wages for labor, but that no longer receive war prices for their products. World-wide economic conditions have brought about a readjustment of commodity values everywhere. A buyers' market is at hand; costs must be hewn to the line. Smaller margins

mines in this country at the present time; approximately 2000 of these are without railroad connections. They may be roughly divided into shaft- and adit-mines; in each case it is necessary to haul the ore to the railroad-spur for transportation—the most expensive operation connected with the production in these mines. For years it has been customary to use two-horse teams in this work. Obviously, this is an expensive method, as a man and team can deliver only from 5 to 8 loads per day over an average haul.

Recently one mine operator made some vitally inter-

A 5-TON TRUCK HAULING GOLD ORE AT THE PORTLAND MINE, AT VICTOR, COLORADO

of profit necessitate, among other things, quick and economical transportation.

During the past two or three years methods of haulage around mines have been undergoing a gradual change, incident to the changed demands of industry. A striking illustration of this evolution is the introduction of the motor-truck to overcome the handicaps of inefficient transportation by human or animal power. It is obvious that the economical conveyance of such material as ore requires mechanical power, as the distance from the mouth of the mine to the mill, where the ore is reduced, is often considerable.

In the mining of coal there has been a tendency of late to motorize transportation. There are about 4000 coal

esting investigations to show the faults of this method as compared with motorized service. On a half-mile haul he stated that his two-ton truck carried an average of 77 tons in $4\frac{1}{2}$ hours; this was made possible, in a measure, by reason of excellent facilities for handling the coal at the pit, where the coal was loaded by means of a bucket-conveyor. It would have been necessary to equip three to four teams with specially-designed dump-bodies to have done the same amount of work.

Inasmuch as many of the trucks in the mining industry are operated independently, no well-defined scheme of routing is possible. Frequently, on this account, a long wait occurs at terminals when a number of trucks arrive at the same time. This is especially likely to occur if the end of the chute is low, thereby interfering with the loading.

It is important, therefore, that the supervisor of

*An abstract of an address delivered before the American Mining Congress at Chicago, on October 20.

traffic develop and encourage as far as possible the adherence to a regular schedule of trips to the mines. He should emphasize the fact that the lack of storage-capacity may result in delaying production if trucks fail to appear on time. When trucks are operated by one company, hoppers of sufficient capacity enable the operator to maintain regular schedules and avoid lost time on the part of the trucks. For this reason the design and construction of the loading facilities at the mine should be carefully considered. To secure efficiency the distance traveled by motor-truck from the mine to the railroad-spur should not, in general, be so long that a round-trip cannot be made in an hour.

Generally the mines of the type to which I have just referred are provided with adequate tipples. This simplifies the problem of loading the trucks; the transfer of the load into the freight-car is frequently more troublesome. However, where the smaller mines are in the neighborhood of larger ones with fully equipped railroad-loading facilities the ordinary dump-body can be advantageously used in connection with the elevated platform. Generally speaking, no more than one minute should be consumed in loading and not more than 3 or 4 minutes in unloading. Where the same work has to be done by hand, 20 to 30 minutes is required for unloading. On the other hand, by means of a hydraulic hoist operated by the motor in the vehicle, the body is raised to an angle of 40° and the load is dumped by gravity through apertures at the rear; the bed is emptied usually in 30 seconds. To facilitate unloading, motor-wagons also are designed so that the contents may slide through side or corner exits. Power-trucks generally are equipped with iron or steel chutes, one end of which is attached to the vehicle, while the other is to discharge at the desired point. It is significant that the products from approximately 3300 mines are being conveyed by motor-trucks or wagons at the present time.

In the mining of copper, lead, and zinc, the methods employed are almost identical with those used in coal mines. The quantity of supplies and machinery required for efficient mining and milling of such ores is much greater than that necessary for extracting an equal tonnage of iron ore or coal. Many operators are obliged to transport both their products and supplies to and from their local warehouse by motor-trucks, inasmuch as the tonnage shipped from any mine frequently is not great enough to make it profitable for the railroad to build side-tracks.

Out on the Pacific Coast an engineer converted a motor-truck into a locomotive for transporting standard-gauge flat-cars used in the reconstruction of the 1400-ft. tunnel at San Rafael for the Northwestern Pacific Railway. It was imperative to avoid the nuisance from smoke and gas, which would attend the use of an oil- or coal-burning locomotive; on this account a searching investigation for an adequate substitute was made. The use of a motor-truck, the gauge of which was about the same as that of a standard railway track, was found to be the most feasible solution of the problem at hand.

With comparative ease this locomotive-truck has hauled two 40,000-lb. capacity standard-gauge dump-cars and two 60,000-lb. capacity flat-cars into the tunnel on a 7% grade at one time. This is a more severe service than was originally planned.

In general the carrying capacity of the motor-truck in transportation of material from mines ranges from $3\frac{1}{2}$ to $7\frac{1}{2}$ tons. Frequently, a motor unit is used for hauling, not only its own load, but that of one or more trailers, with the result that the capacity of the machine is increased, without undue strain or distress, as much as three-fold. Another form of trailer system is that in which a tractor is the motive unit; it draws two trailers, each with a capacity of $7\frac{1}{2}$ tons. The tractor is often equipped with a bed capable of bearing 5 to 7 tons, which increases the total capacity to more than 20 tons. The speed of such a combination ranges from 8 to 12 miles per hour on roads or trails, the gradient of which is as much as 15 to 20%. The 'displacement' value is roughly figured at 15 teams.

The superiority of the motor-truck over the team is revealed in an instance where the former travels 100 miles in a day—two round-trips of 50 miles each—delivering an average of 15 tons. The team, on the other hand, hauling only 3 to $3\frac{1}{2}$ tons, requires 4 days under favorable conditions to make two round-trips. At the conclusion of this period of service the truck is as good as at the start, while the team is worn out, incapable immediately of further sustained work.

Unquestionably, operating costs can be reduced measurably in the mining industry through proper driving and routing. Long service is almost entirely dependent on the driver; he is the crux of the problem. It is well, therefore, to instill a feeling of responsibility in the truck-driver. An important question is the size of the fleet that is to be used. If it consists of ten or more trucks it will be found more feasible to hire one or two expert mechanics than to make each driver individually responsible for the maintenance of his truck.

In any event the desirability of schooling drivers is important. Practical demonstration has done more to bring about good results than perhaps any other factor. In addition to the routine mechanical instruction there are many fundamental laws of truck-operation that can be emphasized. A driver may not realize that he is needlessly damaging his truck by using one road in preference to another; even 30 or 40 miles over fairly smooth roads is more economical than 20 miles over trails.

If I were asked to summarize the basic advantages in the application of motor units to the conveyance of ores from the mines I would cite the following:

(1) Haulage of coal from the mouth of the mine to the consumer is made possible under certain conditions. This releases railroad-cars for the through shipments to points at greater distances.

(2) Ore for small mines can be transported to railroad-spurs.

(3) In the mines where deposit is close to the surface

the overburden can be removed as it is stripped by steam-shovel.

(4) Reliable delivery is established for supplies, mine-timbers, powder, etc.

(5) When the emergency arises mine-rescue machinery can be moved quickly.

(6) The elimination of 'camps' by transporting employees between the mine and towns.

In compiling cost-data it is well to remember that the most satisfactory results will be obtained if the costs are distributed evenly over the period represented by the life of the truck; this applies particularly to such items as the interest on investment, sinking-fund or depreciation cost, tires, and maintenance and repair. Interest is

variable. The greatest value of keeping accurate costs comes through a careful analysis of these items; for this work the National Standard Truck-Cost System will be found helpful.

It is easy to neglect recording of service given by tires, thereby losing any dependable information on which to base comparisons for selecting further equipment. The advantage of recording every mile that each tire covers is obvious.

Manufacturers advocate a liberal use of oil and grease; in fact, they encourage the use of an excess. It has been demonstrated that plenty of oil and grease produces greater working efficiency and is more than repaid by the minimum amount of repair work incident to general

HAULAGE BY MOTOR-TRUCK AT THE WEST END CONSOLIDATED MINE, AT TONOPAH, NEVADA

paid during the sinking-fund period. If this period has been established at only a fraction of the life of the truck, costs during the remaining life will be without interest and sinking-fund charges, and, therefore, cannot fairly be compared with the former costs. For the sake of making monthly or yearly comparisons in motor-truck costs it is also desirable to distribute tire- and repair-costs over the entire period rather than lump them in the particular month they are incurred.

There need be no misunderstanding of truck-operating costs. All of the items of expense are known; motor-truck costs naturally fall into two classes, fixed and variable. The first classification includes the charges for retiring the investment, for interest on the investment, insurance, garage, licenses, and drivers. In the second category of charges we find such items as oil, gasoline, and tires, which are dependent on mileage. Items of repairs, parts, and lost time will perhaps be found the most

overhauling. Lubrication is vital in the maintenance of the machine. Proper lubrication should be made the first consideration in garages that are operated by mining companies.

A RECENT discovery was made of asbestos-bearing rock in Canada, which gives promise of being of considerable commercial value, states a consular report. The deposit is in the serpentine rocks of the Canadian Pacific railway connecting Revelstoke and Arrowhead and is about four miles north of the latter point. The 'Montreal Daily Star' recently announced that a large manufacturing plant for making asbestos products is about to be constructed in the Province of Quebec. About 89% of the asbestos produced in Canada has heretofore been exported to the United States; nearly all of the Dominion's requirements of asbestos has been re-exported from this country.

Breaking the World's Record in Shaft-Sinking

By Walter Fitch, Jr.

Last September the Walter Fitch, Jr., Co. established a new record for rapid work by sinking 427½ ft. in 31 days. The record was made in the Water Lily shaft of the Chief Consolidated Mining Co. near Eureka, Utah. The shaft is vertical and was bottomed at 115 ft. at the beginning of operations. No water was developed during the record-making period.

The surface equipment consisted of two small hoists and two air-compressors. The shaft is 5 ft. 9 in. by

assistance of H. L. Connelly, master mechanic for the Chief Consolidated Mining Co., a dumper was developed that gave entire satisfaction; about 15 seconds was required to discharge the contents. The accompanying photographs show the equipment.

Another important device which we have used in all the shafts sunk by us during the last five years, and which is indispensable for speed, is the suspended steel set, hung below the bottom set by two chain-blocks.

DRILLING IN THE WATER LILY SHAFT AT EUREKA, UTAH, WHERE A WORLD'S RECORD FOR RAPID SINKING WAS ESTABLISHED

15 ft. 6 in. outside dimensions, divided into three compartments, each 4 ft. 4 in. by 4 ft. 6 in. Timbers 8 in. square were used; sets were spaced at 5-ft. intervals, and 2 by 12-in. lagging was used for the outside lining. We hoisted through two compartments, thus facilitating the removal of the rock and the lowering of timber.

We have in the past investigated and used many different sinking-buckets and devices for dumping at the surface, but we have never before obtained the results desired. Conditions seemed favorable in this work for record speed, so that one of our first steps was to devise efficient arrangements for dumping. Through the able

Upon this the timbermen work without interfering with shoveling or drilling operations in the bottom. It consists of a framework of I-beams on which lagging can be placed, in any compartment, to serve as a working platform. It also protects the men in the bottom, and forms a shield to protect the shaft-timbers against the blasted rock. When timbers are being placed the steel set is lowered sufficiently to allow the placing of one set at a time. Before blasting, it is drawn up tight against the bottom of the timbers.

Hoisting was done without cross-heads, but with the use of non-rotating ropes. The compartments were

partly lined to prevent the buckets from striking the timbers. It is surprising to observe how smoothly the buckets travel under these conditions and how the avoidance of cross-heads in shallow shafts adds to the speed and safety of operations.

Another detail that we considered carefully was the 'bonussing' of the workmen. We fully expected to make more than 350 ft. per month; therefore, to base the bonus upon the ordinary speed of sinking would, through excessive awards, have increased rather than decreased costs. A great proportion of the speed was obtained through the efforts of the men and the goodwill and enthusiasm displayed by them; but on the other hand the avoidance of lost motion and the efficient planning made the labor unusually effective. This is one of the reasons we were able to obtain the services of the best workers. It is possible that these same men could have worked as hard and perhaps have made only a fraction of the progress under less favorable conditions. Needless to say, the following bonus, commencing at 212 ft., did not appeal to the miners at first; but when they saw the sets going in at the rate of three per day they realized the possibilities and applied themselves with renewed spirit. The regular wage-scale was: shaftmen, \$5.25; hoistmen, \$5; topmen, \$3.75.

The following schedule of bonuses applied only to men working a full month:

Progress made in 31-day period, ft.	Shaftmen, tim- bermen, and shift-bosses	Hoistmen and topmen
212	\$15	...
262	30	\$15
287	45	...
312	60	30
337	75	...
362	90	45
387	105	...
412	120	60
437	135	...
462	150	75

As the shaft was situated six miles from Eureka it was deemed advisable to take the men to and from work by motor-truck rather than camp them near the shaft. Small temporary camps are unpopular and, under such conditions, it is difficult to retain some desirable workers. The monthly turn-over of labor speaks for itself; there were but four changes made during this period. The crew made short work of any slackers. Men work more efficiently for a contractor for the reason that, as a rule, they can earn more money and make a better 'showing'.

The formation through which the shaft passed consisted of porphyry with the last 60 ft. passing through limestone. The unfavorable feature of the porphyry was its blocky and sometimes sticky condition. The blockiness caused over-breakage, and consequent difficulties in timbering, besides additional shoveling. The stickiness retarded the speed of drilling. In a second 31-day period we almost equalled this record with an advance of 416 ft. through hard limestone; here we overcame the additional hardness by the use of stronger

powder. Hercules Gelatine LP powder, 35% strength, was sufficient in the porphyry, whereas some 50% gelatine was used in the limestone.

After blasting, the gases were replaced by fresh air, conveyed through an 8 in. galvanized pipe from a blower on the surface. This interval, of about 20 min., was set aside for lunch.

Seven Denver Rock-Drill company's Waugh Clipper-55 drills, one Ingersoll-Rand DCR 13 drill, and one Sul-

HEAD-FRAME SHOWING THE ARRANGEMENT OF DUMPING DEVICES AND CHUTES

livan DP-33 air-tube rotator drill were used during the course of the month; an average of five machines was in operation each day. Hollow hexagonal drill-steel, $\frac{3}{4}$ -in. size, with a double-taper bit, was used.

The fact that we were able to perform a complete cycle, that is, drilling, shoveling, hoisting, and timbering each shift instead of every 24 hours, as is the usual custom, added appreciably to the daily footage. We have found three short rounds each day to be more efficient than one or two longer ones. The accomplishment of the

record was helped materially by the co-operation and encouragement given by the officials of the Chief Consolidated Mining Co. J. D. Matheson, general foreman, and Henry Jarvis, shaft-foreman, deserve great credit;

DETAIL OF DEVICE FOR DUMPING BUCKETS

it was through their efforts and skilful supervision that the results were made possible.

The following table summarizes the details of the record-breaking operations:

Distance sunk, feet	427 1/2
Period, days	31
Size of buckets, cubic feet	17
Powder used per foot, pounds	15.25
Average advance per day, feet	13.80
Buckets hoisted per shift	72.5
Sets of timber per day	2.8
Timbermen per day	4.8
Shaftmen per shift	5.7
Holes drilled per round	23.9
Rounds per day	3.0
Delay in 31-day period on account of repairs and power failures, hours	13.0

Gold Refining

*Gold produced from mines in general is associated with impurities, some of which are present in the ore; others are added during the processes of extraction and recovery. Base metals include copper, lead, bismuth, arsenic, and zinc; precious-metal 'impurities' include silver, platinum, and other members of the platinum group of metals. Refining has as its object the removal

of these, for they often have an injurious effect on the physical properties of the gold, rendering it unsuitable for coinage and other purposes. Refining methods may be wet, electrolytic, or dry. These methods have been designated as inquartation, parting, or refining; but as all have the same object in view, it will be sufficient to call them methods of refining only. The composition of the gold that is produced from various parts of the world differs greatly, and several methods of refining have resulted. The wet processes are most suitable with bullion in which the ratio of gold to silver is small. Otherwise much silver has to be added, and extra expense involved. The electrolytic process is one that is suitable for treating gold alloys in which the precious metal is in large excess; it was developed in the North German refinery, at Hamburg. The anodes are made of sheets of the impure gold alloy or bullion, and the cathodes of pure sheet-gold. The electrolyte is a solution of gold chloride, mixed with an excess of hydrochloric acid, or a solution of any salt such as sodium chloride, which forms double salts with gold chloride. The electrolyte is maintained at strength by the occasional addition of gold chloride. During electrolysis the gold and most of the other metals go into solution, but on account of the low current-densities used, only gold is deposited on the gold cathodes, and of a fineness that is seldom under 999.8 parts per 1000.

In the dry processes of refining, the gold bullion is treated when in the molten state, the idea being to add some substance that reacts only with the impurities present and that leaves the gold unchanged, except for slight mechanical losses. It depends on the property of chlorine gas to convert the silver as well as the base metals into chlorides, without attacking the gold. The base-metal chlorides escape as gas, whereas the silver chloride collects on the surface of the gold as a liquid. The refining is conducted in clay crucibles, which are enclosed within graphite crucibles, to avoid loss of metal in case of accident. The clay crucibles are glazed internally with borax, to prevent the chloride of silver from penetrating. Chlorine is delivered into the molten gold by means of a clay pipe, which passes through a loosely fitting clay cover. The chlorine is generated from manganese dioxide and hydrochloric acid in a stoneware vessel.

The gold is charged into crucibles that have been heated previously; when it is molten a few ounces of borax is added. The clay pipe, the end of which has been heated, is then lowered into the metal and chlorine is admitted. The base-metal chlorides are immediately given off as vapor, which ceases as soon as these metals have been volatilized. The crucible is removed from the furnace and the gold is allowed to solidify; the silver chloride remains molten for some time, and is poured off; the gold is then cleaned and re-melted. Its fineness varies from 991 to 997; by repeating the operation, more silver is recovered. Of the gold originally present in the bullion, 98% is recovered, 2% going to the silver. This is recovered from the chloride by subsequent treatment.

Storage-Battery Locomotives in Metal Mines

By E. V. Daveler and R. E. Renz

*INTRODUCTION. The use of storage-battery locomotives for haulage in the metal mines of the West has been increasing steadily since 1913. The demand for more efficient haulage has resulted in operators giving serious consideration to this phase of the mining operations. The different methods of haulage may be classed as follows: hand tramming, mule-tramming, trolley-locomotive haulage, and haulage by storage-battery locomotives. Hand-tramming and mule-tramming, of course, always will have their own field when the tonnage from any one level is not sufficient to warrant the use of haulage by motor. Trolley-locomotive haulage is well suited to long hauls underground where there is a large tonnage and ample head-room, and in ground that is readily held in place. The storage-battery has its particular field in drifts or haulage-ways that have minimum head-room; it has a wide range in the amount that can be hauled; and it can be moved easily from one level to another when operations demand. It can be adapted to the particular fields of any of the three other common methods of underground haulage. In considering the applications of haulage with storage-battery locomotives, the authors of this paper will consider especially mines in which they have had experience.

In the Butte & Superior mine at Butte, Montana, underground haulage with storage-battery locomotives has been very successful. The mine has been opened down to the 2300-ft. level, with mining operations carried on from the 800- to the 2300-ft. levels in the last nine years. The orebodies are wide and the ground is heavy, causing a continual shifting of the grade on the haulage-levels and making it difficult economically to maintain a constant height of the drifts and cross-cuts, which, accordingly, become narrow and low.

In the early part of 1913 it became evident that in order to deliver the required tonnage to the one shaft then operating, some form of power-haulage was necessary. Hand-tramming, due to the varying grade of the levels, had become inefficient; in fact, in some places it was impossible for trammers to push one loaded ear. A study of conditions showed that, from a standpoint of safety, trolley-motors were out of the question, on account of the low drifts, and that the cost of upkeep of the trolley-system would be prohibitive. The low drifts made a trolley-system dangerous; also the moving ground increased the fire-risk. The alternative method of tramming was by storage-battery locomotives, which at that time, early in 1913, were in the experimental stage. However, it was decided to try the system, and two

Jeffrey storage-battery locomotives were purchased early in 1913, and two additional locomotives in 1914.

Following is a description of these locomotives:

Weight of chassis, tons.....	21½
Weight of chassis with battery, tons.....	30½
Gauge of rail in.....	18
Wheel base, in.....	36
Length of locomotive, ft.....	11
Maximum width, in.....	32
Draw-bar pull, lb.....	1500

These locomotives were equipped with two sets of batteries, one to be used while the other was being charged, thereby affording continuous service for the locomotive. Each battery consisted of 63 No. A-4 Edison cells having a capacity of 150 ampere-hours and an average voltage of 75. These locomotives were equipped with two motors, each geared to a separate set of drive-wheels by means of worm-gears in one reduction. With this construction it was possible to keep the maximum width down to 32 in. The speed of the locomotive is 4 miles per hour. The control is standard series-parallel with resistance-points between.

PROVISIONS FOR SAFETY. For a year the operations were entirely satisfactory; then it was discovered that in wet levels the storage-battery cells would 'ground' and that, due to electrolysis, the steel containers were being corroded, causing leakage. This was due to insufficient insulation between the cells and the battery-box, a difficulty that was remedied by mounting the individual cells on porcelain blocks. This method of insulation is still in use, although the Edison company has devised a method of insulation by rubber bushings, which apparently is as satisfactory.

Early in 1917 the work required of the locomotives became particularly heavy and it was necessary to change the A-4 batteries before the 8-hour shift was finished. These cells were then replaced with A-6 cells, the battery having an ampere-hour capacity of 225. The number of cells to a battery was increased from 63 to 66, and later to 72, which is the greatest capacity we can accommodate on our present motors. This has improved the efficiency of the locomotive considerably, as the voltage is more successfully maintained at the end of discharge, and greater loads can be moved at higher speeds. At the present time the company has nine locomotives, each equipped with two sets of batteries. This discussion has given a general idea of the equipment and necessary changes from time to time.

One important advantage of storage-battery locomotives is the comparative freedom from electrical troubles, such as grounds and shorts in armatures and field-coils. The voltage is only 75 to 80, so there is little danger from accidental contacts. During the entire operations at the Butte & Superior mine there has been no accident of

*A paper read before the 10th annual congress of the National Safety Congress.

an electrical nature on the locomotives. As originally built, leads were connected to the locomotives by means of terminal screws and there was always the possibility of the motorman burning himself when changing batteries; there was also the liability of failure to tighten terminals, with consequent loss of power and eventual burning. This has been obviated by substituting a plug-type contact, thereby avoiding all danger from burning and poor contact. Another bad feature was the danger that the cover of the battery-box might be jarred out of position and might catch on timber posts; in that event the life of the motorman would be endangered. This happened in one case, but as the locomotive was traveling slowly the motorman shut-off the power and escaped serious injury. This has been remedied by bolting angle-pieces to the battery-box, so that the cover can be put on in only one way and can then be held securely in place. As originally furnished, switches, fuses, and instruments were mounted on a panel in front of the motorman. This has been changed and all exposed parts have been enclosed in metal boxes of substantial construction. Because of the small width of the locomotives and drifts, part of the motorman's body might extend over the side of the locomotive; there was danger that he might be caught on timbers and badly hurt. To prevent this, all locomotives are now equipped with a sheet-iron guard, so that the motorman cannot sit with part of his body extending over the side of the locomotive. Locomotives are equipped with modern head-lights and 94-watt focusing-type lamps. All locomotives are equipped with foot-bells, and as the speed is slow few accidents occur.

CARE OF THE LOCOMOTIVE. The locomotives furnished were not equipped with charging-meters, but we have added Sangamo ampere-hour meters with compensating shunts; these register the ampere-hour discharge and measure the proper charge, automatically cutting-off the charging-current at the right time. This helps in maintaining the batteries in proper condition and reduces the consumption of distilled water. The most regular and careful inspection and attendance must be given to the batteries; they should be regularly filled with distilled water; they must be kept free from moisture and dirt; and the tops must be well covered with vaseline to keep salts from 'creeping' and short-circuiting the terminals. Batteries should be cleaned regularly, and at periods of from 12 to 18 months the old solution should be poured out and all sediment removed by washing with clean old solution; water should not be used for washing, as it removes deposits from the plates, which is detrimental.

The batteries, after cleaning, should be filled with new solution and discharged to zero. The current is then reversed and the batteries are fully charged; this will bring the cells back to nearly full capacity. In handling the solution great care should be taken, as a 22% solution of hydrate of potassium is used; it is decidedly corrosive, attacking the skin and eyes severely. Rubber gloves and aprons, and goggles should be worn when working with the solution. The average life of the batteries is three years.

At the Butte & Superior plant one electrician cares for all the locomotives, making daily inspections. Charging is done on each level where locomotives are working; locomotive-barns are equipped with charging-panels, water-filling equipment, and chain-blocks with crawls for changing batteries. The distilled water is made on the surface at a cost of less than $\frac{1}{2}$ ¢. per gallon, and approximately 20 gallons is used per day for 18 sets of batteries. The charging-pressure varies from 125 to 135 volts and is supplied from small motor-generator sets.

SERVICE OF LOCOMOTIVES. At the Butte & Superior mine the average length of haul is approximately 500 ft., varying from 200 to 3000 ft. About ten cars are hauled per trip, the weight of ore and car being 2250 lb. The cars are equipped with roller-bearings.

OPERATING-COSTS. The cost of operation has been high for several reasons: first, irregular grades for the tracks; second, short hauls with a small number of cars; third, conditions in parts of the mine that are not conducive to long life of the battery.

The following statistics cover the year 1919:

Number of locomotives operating.....	9
Cars of ore hauled.....	805,372
Cars of waste hauled.....	132,415
Average haul of car of ore, ft.....	800
Average haul of car of waste, ft.....	717
Cost of power per car hauled.....	\$0.00410
Cost of repairs for locomotive per car hauled.....	0.03205
Cost of motorman and helper per car hauled.....	0.00900
Total	\$0.10515

Underground haulage with storage-batteries in metal mines is well exemplified by the Butte & Superior practice. In Butte both the Elm Orlu Mining Co. and the Anaconda Copper Mining Co. are using storage-battery locomotives with success. From the standpoint of safety the storage-battery locomotive is probably the most satisfactory machine for underground haulage.

FLUORSPAR (fluorite) is composed of calcium fluoride; it is usually purple, green, yellow, or white, rarely colorless, states an Imperial Mineral Resources bulletin. The chief use of fluor spar is as a flux, especially in the manufacture of steel. It has been used in increasing quantities in recent years in the basic open-hearth process, in which it acts as an efficient flux. Another important metallurgical use is in the preparation of electrolytes employed in the reduction of aluminum ores and in the refining of lead and of antimony. Fluorspar is used also for enameling purposes, for making agate-ware and opalescent glass, and for cementing purposes in the manufacture of emery-wheels and carbon electrodes. Transparent and colorless fluor spar is used in the manufacture of special lenses and prisms. Fluorspar is prepared for the market by hand-sorting, crushing, screening, washing, jigging, and fine grinding. The separation from zinc-blende, with which it is frequently associated, is effected by flotation. It is marketed in three grades. The silica limit for lump and gravel is 6%; for fluor spar to be used in the ceramic industry, 3 to 5%; to be used in the manufacture of hydrofluoric acid, 1%.

REVIEW OF MINING

ZINC PLANTS IN OKLAHOMA TO RESUME OPERATIONS

The Bartlesville Zinc Co., at Bartlesville, Oklahoma, has announced the immediate re-opening of its zinc smelters that have been closed since spring. According to reports, 700 men will be employed. The company owns three plants containing in all about 1800 retorts.

PRODUCTION AT COBALT

During the month of October the silver mines at Cobalt and in the districts of Gowganda and South Lorrain in Northern Ontario produced close to 900,000 oz. of silver. The Nipissing was the largest producer, with an output of 340,000 oz. The physical condition of the Nipissing has improved during the past two months through the development of important ore-shoots in a new section of the mine. One narrow ore-shoot opened during October contains ore assaying 2500 oz. per ton. During the month, according to official advice, the Keeley Silver Mines in South Lorrain produced 102,000 oz. of silver, 36,000 oz. being in concentrate from the 20-stamp mill, and 66,000 oz. in high-grade ore. Developments are exceptionally favorable, and ore-reserves are estimated to contain 550,000 oz. Work is under way for the purpose of tracing the ore-shoots to greater length, and the mine is declared to be well established as a steady producer. The Conlagas Mines closed its fiscal year with a production of close to 1,200,000 oz. of silver, or approximately 20% above the record for the preceding year. The company paid \$200,000 in dividends, as compared with \$500,000 in the year preceding. The re-treatment of tailing has been suspended for the winter months, and work is now confined to the handling of ore from the underground workings.

NEW WAR MINERALS RELIEF BILL IS PASSED

The bill providing for more liberal interpretation of the War Minerals Relief Act has been passed by both houses of Congress. The final vote in the House of Representatives was taken on November 16. The bill was subjected to considerable opposition, led by Stafford, of Wisconsin, who argued that it would open the way to unmerited claims, but the bill was ably defended by Chairman Rhodes of the House Mines and Mining Committee, Chairman Slinnott of the Public Lands Committee, and others. The opposition was successful in making a point of order against the bill on the ground that the Mines and Mining Committee had no jurisdiction, as it involved appropriations which must be handled by the Appropriations Committee, but proponents of the measure were able to secure the adoption of amendments to accomplish the aim of the bill, which is to enable the War Minerals Relief Commission to pass on claims barred by administrative rulings.

DIRECTOR-GENERAL OF RAILROADS ASKS FOR A RECONSIDERATION OF THE GOLD HUNTER RATE-CASE DECISION

The Director-General of Railroads has requested the Interstate Commerce Commission to reconsider its decision in the case of the Gold Hunter Mining & Smelting Co., in which the commission found that charges on ores and concentrates

from Sunset and Mullan, Idaho, to Salda, Colorado, were unreasonable. The Director-General asks that the commission hold that both the gross-value rule and the charges resulting therefrom, and the Salda rate are not unreasonable; also that the undercharges resulting from the deliberate and intentional mis-billing by the complainants be not waived, but be collected; and that the commission should make clear that no shipper, with or without collusion of a railroad, may with the sanction of the commission violate tariffs on the plea that in the opinion of the shippers such tariffs are unreasonable. The Director-General says the commission's recent report "cannot fail to be considered little short of an inducement of such violation".

COPPER SHARES IMPROVE

Copper shares have responded to the better feeling in the market for the metal. They were at their bottom prices last December—20 representative issues dropping to 21.83. They rallied to 28.78 in May, only to fall back again in August to 22.39. During October and so far in November they have fluctuated within a narrow range. Anaconda, Calumet & Arizona, Calumet & Hecla, Utah, Ahmeek, and Cerro de Pasco are all up over 10 points from the low of the year, while the balance of the list has registered substantial gains.

Virtually all the major properties are closed down and they will probably not resume until well into 1922. It is only a question of time when the surplus will be reduced to such a figure that mines will again be re-opened. The worst period has passed, and the market is discounting better days for the industry. Below is a list of important copper shares showing the current high prices compared with 1921:

	Nov. 21,	1921 low	Advance
Ahmeek	55 1/2	40	15 1/2
Allouez	24	16	8
Anaconda	45 3/4	31 3/4	13 5/8
Calumet & Arizona	53 1/2	41 1/2	12
Calumet & Hecla	260	210	40
Cerro de Pasco	34 1/2	23	11 1/2
Chino	27 1/8	19 1/2	7 5/8
Copper Range	35 3/4	27	8 3/4
Greene-Cananea	25 1/2	19	6 1/2
Inspiration	38 1/4	29 5/8	8 5/8
Isle Royale	22	16 1/4	5 3/4
Kennecott	24 5/8	16	8 5/8
Miami	25 1/2	15 3/4	9 3/4
Mohawk	53	43 1/2	9 1/2
Old Dominion	25	15 3/8	9 5/8
Quincy	42 1/4	33 1/2	8 3/4
Utah	59	41 1/8	17 7/8

MINERALS SEPARATION CLAIMS \$12,000,000 FROM BUTTE & SUPERIOR

Damages of almost \$12,000,000 have been named by the Minerals Separation North American Corporation as due it from the Butte & Superior Mining Co. This estimate by the Minerals Separation management is placed before the master who has been taking testimony in New York in the

long drawn out litigation between the two concerns. A year ago, during court proceedings at Butte, oral estimates were made to the effect that Minerals Separation then figured its damages at \$20,000,000. Since that time, however, the plaintiff has had some official data compiled by the Butte & Superior accountants showing earnings and their source in detail which have enabled a revision of earlier claims. It is understood that the amount mentioned, \$11,900,000, was arrived at as a 'measure of damage' as representing the difference between the recovery possible by water concentration and by flotation.

DAVIS-DALY COMPANY SUSPENDS OPERATIONS AT COLORADO MINE AT BUTTE

Official announcement is made by the Davis-Daly Copper Co. that all operations are to be suspended at the Colorado mine on November 20. The Hibernia mine, a silver-lead-zinc property, will continue to operate. The shutting down of the Colorado mine will result in a complete suspension of copper production, and will also substantially affect silver output. The Colorado mine accounted for the entire copper production of 13,564,064 lb. last year. Of the 902,978 oz. of silver produced in 1920 the Colorado mine accounted for 539,000 oz., and the Hibernia 362,000 oz., of which 358,425 oz. was from lease ore.

The failure of the negotiations between East Butte and Davis-Daly, that had as their object the merger of the two companies through an exchange of East Butte stock for Davis-Daly shares, does not indicate, as recent reports stated, that Davis-Daly has any immediate intention of erecting a smelter to handle its own ores. Such a step under present business conditions has not even been thought of by the Davis-Daly management. Under present high construction costs a smelter large enough to handle the maximum tonnage that the Davis-Daly mine could deliver would cost several million dollars. With conditions in the copper-metal market as they now are, the Davis-Daly officials consider it the better part of wisdom to continue to have the smelting done by East Butte, which arrangement has been in effect for several years.

Davis-Daly has recently been turning out copper at the rate of around 600,000 to 700,000 lb. per month, while silver output has been averaging about 140,000 oz. per month. During the March quarter, copper amounted to 2,043,025 lb. and silver to 989,526 oz. Last spring Davis-Daly discontinued practically all work at the property not immediately essential, and working forces were cut to the minimum practicable for single-shift operation, six days per week.

A. S. & R. AFFAIRS

The American Smelting & Refining Co. has no present intention of emulating its leading competitor, the Anaconda Copper company, in finding an outlet for its copper production through ownership of brass- or wire-mills, although the subject has been given much thought. At the moment, lead constitutes the Smelting company's 'best seller'. It, of course, has no difficulty in disposing of all the silver that it produces. But copper and zinc have not responded to the point where increased operations may be ordered, although the company has been getting its full quota of recent copper sales.

The El Paso and Hayden copper smelters are idle. The Perth Amboy smelter and refinery have not been operated for more than a year, but could be readily blown-in if the Baltimore refinery had more than it could handle. The Tacoma plant, handling chiefly high-grade ore, has been able to maintain operations at about 75% of capacity. Kennecott and other Alaskan properties ship to that point, while the South American output from the Guggenheim properties has also been going to the Tacoma refinery. The Hen-

rietta smelter, with two blocks of retorts in operation, constitutes the only zinc unit running, with the single exception of a plant for the production of zinc dust used in cyanide operations. The company has been forced to cease its tin production, as present low prices have made it impossible for Bolivian tin mines to continue profitably.

MINERALS SEPARATION ANSWERS COMPLAINT BROUGHT BEFORE THE FEDERAL TRADE COMMISSION

The Minerals Separation North American Corporation, respondent named by the Federal Trade Commission in its amended complaint against owners of patents on the flotation process, have filed answer in which a more or less sweeping denial of many of the charges is contained. The answer does admit "that by reason of its acquisition by ownership or beneficial interest of * * * patents in respect to processes, respondent now claims and asserts * * * a monopoly and the exclusive control of the processes for separation and concentration of ores covered by the patents * * *" The company claims ownership of some 50 patents covering flotation under which it has granted 140 licenses with aggregate tonnages of ore milled and in part treated under these licenses aggregating 28,000,000 tons per year. Allegations of stifling or restraining trade through its licensing policy, Minerals Separation denies.

Replying to charges of favoritism being shown in granting certain licenses, the Minerals Separation answers that on four occasions special terms were given to "meet special and unusual conditions".

These were:

(1) About February 1915, to the Anaconda-Inspiration group of mines when they agreed to use and pay large sums regardless of the outcome of then existing litigation over patents;

(2) In August 1915, when the St. Joe and Doe Run lead companies entered into agreement guaranteeing extensive use and payment of large sums to Minerals Separation at a time when basic patents had been declared invalid by United States Circuit Court of Appeals;

(3) About January 1916 the Desloge Lead Co., controlled by same interests as St. Joe and Doe Run companies, also agreed similarly as the other two, although basic patents were then as well declared invalid;

(4) About June 1916 special terms were given to Colusa-Parrott Mining & Smelting Co. "because the quality of its dumps, the low recovery, and the narrow margin of profit to said company made it equitable at the time, in the opinion of Minerals Separation, Ltd., to do so".

General denial was made by Minerals Separation to charges that it transported materials or apparatus, that it leased or sold equipment or engaged in interstate commerce. Also, that it had competition or that others lawfully engaged in similar business. As to its opinion regarding dominating the field of flotation, the Minerals Separation answer leaves no doubt in the statement: "If there are flotation processes not covered by (our) patents * * * respondent denies that they are important".

ARIZONA

Jerome.—The United Verde company is working steadily on its plans for providing modern and economical methods for handling its ores when the time shall arrive for resuming production. A contract has been let for 35,000 yd. of excavation and 18,000 yd. of fill on the site of the new ore-crushing plant, on the side of a low hill just west of the Clarkdale smelter. This work of preparing the ground is expected to require 100 days. At Clarkdale the company has completed the necessary buildings for its new Cottrell smoke-treating plant and has started erection of a separate stack.—James S. Douglas, president of the United Verde

Extension, is working toward lower freight-rates to the Pacific Coast, with expectation of shipping most of the company's bullion to the East by the water route if a tariff of \$5 per ton can be secured from Jerome to Los Angeles. He compares this rate with the \$9 per ton that used to be paid to New York by the smelters at Douglas.

CALIFORNIA

Grass Valley.—Production from the Idaho-Maryland group of mines is increasing. The old Eureka vein that produced bonanza ore years ago has been entered in virgin territory. It seems probable that the company will undertake the sinking of a new central working-shaft within a few months.—At the Central mill of the North Star Mines Co. 60 stamps are dropping regularly on ore coming from below the 5600-ft. level; 450 men are employed. The electric power-line to the Boundary mine west of Grass Valley is nearly finished. Modern hoisting and pumping equipment is

of the richest opened in this section. Samples assay as high as 1400 oz. per ton. This company started operations two years ago on leased property; it now owns or controls 14 claims, on which five distinct veins have been exposed. The same company is also operating the Wigwam adjoining the Grant County mines.

Glenwood Springs.—Applications for patent to a large number of oil-shale placer claims in Garfield county have been made recently. The Ventura Consolidated company and representatives of the Pure Oil Co., who have contracted for a large acreage of oil-shale placer claims, have been using a diamond-drill proving up the land. Three diamond-drill holes have been put down to a depth of 800 ft. and a rich oil-shale has been developed.

Idaho Springs.—The P. T. mine, on Chicago creek, located and operated in the earlier days by Tete Theobald, now deceased, has been taken over by Burkhart & Co. A compressor to be operated by electricity and a hoist are being

Colorado Shaft of the Davis-Daly Copper Co., at Butte

to be installed to make possible the economical mining of ore already blocked-out.

French Gulch.—New milling equipment is being installed at the plant on the Van Ness property. A better recovery is expected as a result.

Randsburg.—The California Rand Silver, Inc., is rapidly completing its 100-ton flotation plant. Murray N. Colman is superintending the construction and will operate the plant. Shipments of high-grade ore to the smelter continue at the rate of 10 cars per week.—The North Rand Mining & Milling Co. has received its compressor, receiver, air-drills, and other equipment. The temporary gasoline hoist will be replaced by an electric hoist, preliminary to deeper exploration.

Sonora.—E. H. Althoff and W. G. Busick have taken a lease and option on the Magente group. A number of promising veins have been disclosed and further prospecting is planned preliminary to starting a new shaft.

Weaverville.—The Bonanza King 20-stamp mill will be started as soon as sufficient water is available to operate the electric-power plant. A good reserve of ore has been blocked-out, according to reports.

COLORADO

Boulder.—The Caribou Hill Mining Co. is hoisting rich silver ore from a shoot pronounced by mining men to be one

installed.—Milling machinery formerly in use at the Scotia mill at Silver Plume has been installed in the mill at the Mendota mine of the Wasatch M. & M. Co.; the plant will shortly start treatment of ore, thereby saving hauling expense.

Leadville.—The mill of the Yak Mining, Milling & Tunnel Co. is being remodeled under the direction of E. L. Hartwell, superintendent, who is associated with the A. S. & R. Co. The low-grade ores will be treated by concentration, flotation, and jigging, and experimental tests are said to have shown that losses will average less than 20% instead of 40 to 50%. The mill for the present will be experimental with a view to determining the best milling practice. A successful result should be of far-reaching value to mines of the Leadville district containing low-grade ores.

Telluride.—Lessees on the Shamus O'Brien are mining and shipping ore to the smelter returning from \$80 to \$100 per ton.—Lessees on the New Dominion are mining ore from a 'paystreak' 14 in. wide, sampling \$15 to \$20 per ton.—High-grade ore sampling 114 oz. silver and 3 oz. gold is under development in the American mine. More men are to be employed.—Milling ore averaging \$15 per ton gold, is being mined from a two-foot streak on the old Suffolk property, where lessees have repaired and improved the mill equipment and are now profitably milling their output.

IDAHO

Coeur d'Alene.—In the first nine months of this year the Caledonia Mining Co. made a profit of \$53,845, chiefly from the leavings in worked-over stopes and drifts, according to Stanly A. Easton, president. The company now has on hand a surplus of \$401,358 which is to be distributed to stockholders as soon as it is known what part of it must be deducted for Federal income and excess-profits taxes. Although no new ore has been found for a long time and there is little hope of finding more, it will take nearly a year to work the good ore still remaining in stopes and dumps. In the nine months the company mined 6963 tons of dry ore, from which 994,095 lb. of lead, 148,051 oz. of silver, and 4757 lb. of copper were extracted. The gross value was \$84,423, the cost of mining was \$7.48 per ton, or \$52.105.

Seven carloads of ore has been shipped by lessees of the Sister mine on Canyon creek, a short distance above Wallace. The last car contained 31 tons and is believed to have been the richest ore shipped. The lessees expect to be able to continue shipments of a carload every two or three weeks. The ore is from a point 930 ft. from the portal of the main adit.

A nine-foot body of lead-silver ore was discovered recently in the east drift of the Lookout mine of the Coeur d'Alene. The ore opened is similar to that found in the upper workings of the Caledonia and Sierra Nevada mines; it carries lead both as carbonate and as galena. The ore-shoot is 300 ft. below the upper adit.

Rocky Bar.—The Idaho Gold Corporation was recently formed at Salt Lake City, Utah, to undertake the exploitation of the Vishnu, Mountain Goat, and adjoining gold mining properties. The two named have a record of production in the 'seventies, when \$80 ore was mined. The additional territory comprises 2½ miles of promising placer ground and important water-rights. Development will be undertaken.

MICHIGAN

Houghton.—Calumet & Hecla, Ahmeek, Copper Range, and Mohawk have successfully developed either power-shovels or stope- or level-scrapers. Calumet & Hecla employed stope-shovels to good advantage in its conglomerate department just before the shut-down last April, and eventually the use of similar devices will be extended to all of its mines and subsidiaries. At Ahmeek the introduction of power-scrapers indicates that the stopes can be carried higher than has heretofore seemed practicable, and, in consequence, drifting on some of the levels was discontinued early in 1920 to permit a more extensive cutting of the stopes. Hereafter new levels can be started farther apart than has been the practice in the past. This in itself will result in a saving in mining costs. Copper Range has developed a combination power-shovel and 'picker', which not only aids handling but makes sorting possible. The shovel throws the rock onto an endless belt, along which stand two or three men who pick out the waste. This type of shovel and conveyor has been successful in the Champion mine, and others will be adapted for use in Baltic and Trilmountain. All of these devices are made in the local shops, for the reason that no standard shovel or scraper is adaptable.

Extensive repairs are under way in No. 2 Gratiot shaft of the Seneca property, preparatory to the resumption of sinking. The old shaft-collar is being removed and a new collar will be constructed. Steel sets will be used and the collar will be concreted through the overburden, a depth of 95 ft. from the surface. The present depth of the shaft is 1420 ft. It will be sunk 1800 ft. deeper, at which point it will be connected with the 3rd level drift, north, from the Seneca shaft. The present hoist will be replaced with one having capacity to operate from 3500 ft., purchased recently from the East Norrie mine at Ironwood. The ma-

chinery already is on the ground. When sinking is under way cross-cuts will be put into the lode from time to time and stations for levels likely will be cut as the shaft deepens.

Much interest attaches to Mayflower's proposed work on the 14th level, where a drift shortly will be started in a northerly direction. Opening work on the 17th level will continue in the main drift south, where an encouraging 'showing' has been found. Operations on the 14th should be attended with fewer difficulties than at the greater depth, for barriers encountered below can be avoided through information obtained on the bottom level. The faults have been fairly well platted and these data will save much unnecessary drifting and cross-cutting on the 14th. For 500 ft. the main south drift from the 17th level has been in good milling ore, only recently cutting a fault which necessitated a cross-cut to the east to again pick up the vein.

The Winona Mining Co. has sold all of its standing saw-log timber near its property to the Pampa Land Co., a newly formed concern, which will establish a saw-mill and tie-mill and eventually a woodworking plant at Winona. The deal involves 20,000,000 ft. of timber. The Winona company has arranged to sell power to the new company and also will allow the new concern to use its electric railway, houses, and other equipment. The deal does not affect the mining rights of Winona, the company still retaining all of its lands and other assets of a mining nature. The establishment of this new industry is expected to make Winona a thriving settlement, which, since the shut-down of the mine, has been all but deserted.

MONTANA

Butte.—The North Butte Mining Co., although not producing copper, is maintaining the nucleus of its organization. Work is confined entirely to development on the 3000-, 3200-, 3400-, and 3600-ft. levels. Expenses are down to a minimum, shift-bosses in many instances acting as miners in carrying on development operations. On the 3400-ft. level of the Adirondack vein a drift 78 ft. long disclosed 38 ft. of ore averaging 4 ft. wide and assaying 4.3% copper and 3 oz. silver per ton.

The Edith May vein on the 3200-ft. level has been drifted on for a distance of 195 ft., of which 69 ft. was in ore of an average width of almost two feet, assaying 4.8% copper and nearly 3 oz. silver per ton. The 3400-ft. level on this same vein was drifted on for 194 ft., of which 88 ft. was in ore of an average width of 2.6 ft., assaying 8.1% copper and 4.3 oz. silver per ton. The 3600-ft. level of the Edith May was drifted on for 217 ft., 58 ft. being in ore assaying 14.6% copper and 6½ oz. silver per ton.

Helena.—The Howard shaft on the Drumheller-Woldson property, near Scratch Gravel, is down 270 ft. For a distance of more than 100 ft. below the 140-ft. level the shaft has been in ore, containing silver, copper, gold, and lead. Some is of shipping grade. The shaft is to be put down 300 ft. before cross-cutting.—At the Fairview mine a 20-in. vein of free-milling gold ore has been exposed.

The Carbon Hill mine, in the Grass Valley district, sent a car of silver ore this week to the East Helena smelter. The ore averaged \$106 per ton.—The Surety and Consolidated lode-claims are under lease and option; a cross-cut is being run at a depth of 80 ft. for the purpose of finding an east-west vein that has not been opened heretofore.

NEVADA

Argentite.—Frank Taylor is sorting ore from the Argentite mine, under bond to the Natural Soda Products Co., for shipment to the Desert mill at Millers. The ore is coming from a drift at the bottom of a 100-ft. shaft.

Carson City.—A hearing is being held before the Public Service Commission of Nevada, designed to bring about a reduction in freight-rates on ore shipments from Nevada.

mines. The conference is attended by representatives of the railroad companies operating in Nevada, members of Chambers of Commerce, the Nevada Mine Operators' Association, and mining men from all parts of the State. According to officials of the U. S. Smelting & Refining Co., high freight-rates on coke and limestone used at the smelters make it impossible to reduce treatment-charges at this time. Mining men have contended that the present high rates have throttled mining in many Nevada districts, and that by making mining costs prohibitive in this way the railroads are losing large amounts of revenue.

Ely.—The Nevada Consolidated Copper Co., during the cessation in production, has been increasing its reserves of high-grade ore through development work. The new body of ore, in the Ruth mine, has averaged close to 10% copper to date; the ore will probably assay more than 6% as mined. Unofficial estimates place the amount of high-grade smelting ore in sight at about 500,000 tons.

Gerlack.—According to A. A. Codd, the recently finished milling plant of the Leadville Mines Co. will be improved so as to enlarge its capacity to at least 50 tons. A new shoot of ore was recently opened on the 350-ft. level of the mine, the ore averaging \$30 per ton. Raises have been put up from the 300-ft. level for over 100 ft. Each shows about the same grade of ore. Considering that there are about 200 ft. of backs, this opens a big orebody.

Pioneer.—The 10-stamp mill of the Mayflower Consolidated company, which recently resumed operation, is now running smoothly. Development, carried on while the mill was being repaired, has opened a long shoot of ore in the Starlight claim, the average content being \$20 per ton. Ore from the Starlight mine is delivered to the mill by a 1400-ft. tramway. W. J. Tobin is manager.

Beno.—George H. Bartlett, judge of the district court, has set December 8 as the time for the hearing of the suit brought against the Cash Boy Consolidated Mining Co., of Tonopah, by the Tonopah Extension Co. The Tonopah Extension charges that the Cash Boy has mined valuable ore from territory owned by the plaintiff and demands damages and costs. The suit is resisted by defendant corporation, which claims that all ore produced was taken from its own workings.

Royston.—Five feet of rich ore is exposed in the bottom of the shaft at the Betts lease on the Hudson mine; 10 tons of ore averaging \$700 per ton was shipped recently to the MacNamara mill. The property is controlled by a new company of which Walker Brothers, of Salt Lake City, are the financial backers.

UTAH

Alta.—During October, the Alta Tunnel & Transportation Co. shipped 170 tons of ore, with a net smelter value of \$6500. Recently additional teams have been secured, and it is expected shipments during the present month and December will be about 500 tons per month. The ore averages about \$35 per ton, net.

Big Cottonwood Canyon.—Exploratory work at the property of the Cardiff Mining Co. has resulted in opening the richest ore ever found in the mine. The new discovery is on the 1100-ft. level. On the 600-ft. level, ore has been found several hundred feet south of the point where it was believed the mineralization extended. An ore-shoot from 4 to 15 ft. wide has been proved by a raise to extend upward for nearly 250 ft.—The gratifying results attending development at the Cardiff property has resulted in more aggressive exploratory work at the Howell, American Metal, Tar Baby, Price, and Reed's Peak properties. The American Metal Co. has completed preliminary work, such as the building of snowsheds, blacksmith-shop, and bunk-house. Work will be carried on throughout the coming winter. At the Price mine, a rich streak of ore recently found gave re-

turns of 350 to 500 oz. in silver, 35 to 45% lead, and 10 to 11% zinc.

The State Securities Commission has granted permission to the Twin Peaks Mining Co. to sell 300,000 shares of stock. The company owns 11 claims upon which all assessment work has been done. The property is situated near the old Maxfield mine. The capitalization of the company is 1,000,000, of which 301,700 shares are outstanding. J. A. Kauffman is president.

Eureka.—C. E. Loose, who owns the controlling interest in the Grand Central Mining Co., has given an option on his entire holdings to Paul Hillsdale. Hillsdale is a son-in-law of Walter Fitch, of the Chief Consolidated Mining Co.; it seems certain that the option was secured for the latter com-

Road Up the Salmon River Valley, in British Columbia

pany. The Grand Central is one of the oldest and best-known mines in the Tintic district. It is situated between the Mammoth and Centennial-Eureka properties, in the western part of the district. The main ore-channel in the Grand Central extends the full length of the property. The mine has produced ore to the value of about \$10,000,000 and has paid \$1,880,000 in dividends. Large quantities of low-grade ore have been developed that will average about \$8 per ton. The mine has been opened to a depth of 2500 ft., with levels at intervals of 100 feet.

Directors of the Iron Blossom Mining Co. have declared a dividend of 2½c. per share, payable on December 20. This will call for a payment of \$25,000 and will bring the grand total of such disbursements up to \$3,300,000. The last dividend paid by the company was in January 1920.

Several of the local mines, including the Tintic Standard

and Chief Consolidated companies, have been forced to curtail shipments of siliceous silver ores, owing to the smelters being over-stocked. The notice to reduce shipments came at a time when the Tintic Standard was preparing to eclipse its past production records; shipments during the first week of November reached 81 carloads or about 4000 tons. During the week ending November 12, the Tintic Standard shipped 69 cars; Chief Consolidated, 38; Victoria, 12; Dragon, 12; Centennial-Eureka, 7; Eagle & Blue Bell, 7; Iron Blossom, 5; Colorado, 5; Swansea, 5; Bullion Beek, 2; Empire Mines, 2; Gemini, 2; Showers, 1; Sunbeam, 1. Shipments the preceding week totaled 191 cars.

The shaft at the Zuma mine has reached a depth of 950 ft. and is being sunk at the rate of 4 ft. per day. The bottom is now in a lime formation and sinking will be continued until the 1200-ft. level is reached.

Park City.—Suit has been filed in the United States District Court at Salt Lake City by Francesco Rospigliosi of New York to foreclose a mortgage for \$30,000 on the property of the Glenallen Mining Company.

Ore shipments for the week ending November 19 totaled 1962 tons, of which the Judge allied companies shipped 934; Silver King Coalition, 603; and the Ontario, 425. The previous week's shipments totaled 1979 tons.

Stockton.—Operations have been resumed at the Muirbrook mine, which is owned by Mrs. Lena Larsen. The ore shipped from this property last year was high-grade; netting from \$2000 to \$2500 per car after deducting freight, sampling, and smelter-charges. Recently a body of high-grade ore was opened on the 200-ft. level, and development has also been resumed on the 500-ft. level. Mrs. Larsen is planning to start exploratory work on the Plono group of claims, consisting of 200 acres, adjoining the Muirbrook property. A boarding-house and blacksmith-shop will be erected immediately.

BRITISH COLUMBIA

Alice Arm.—An 18-ft. vein of ore averaging 34 oz. in silver per ton is being developed at the Moose group, in the Kitsault valley.

Kimberley.—The North Star mine has been re-opened. Work was suspended at the commencement of this year, when the Trail smelter ceased buying ore. Last year this mine shipped 6500 tons of silver-lead-zinc ore to Trail.

Nelson.—Some of the principal mine-owners in the Kootenay district met at Nelson on November 11, and former the Mining Association of eastern British Columbia, for the purpose of looking after the welfare of the mining industry in that part of the Province. The following provisional officers were elected, R. R. Bruce, president; Clarence Cunningham, vice-president; W. H. Burgess, secretary-treasurer; T. W. Bingay, S. G. Blaylock, W. A. Davis, S. S. Fowler, Douglas Lay, J. A. Madden, and W. T. McDowell, executives. R. R. Bruce and J. J. Warren were appointed a committee to proceed to Victoria to interview the officials of the Provisional government on mining matters generally and the present excessive rate of taxation in particular.——O. C. Thompson and W. B. Horton, who have a lease and option on the Utica mine, at Retallack, have cut two new ore-shoots in the lowest workings. One shoot gives 18 in. and the other 24 in. of clean ore. Good progress is being made on the 2000-ft. tunnel, which should cut the orebody at a point 350 ft. below the present bottom.——The Spokane Mining & Development Co. has struck a good body of copper ore at the Monarch group, near Beasley. A cross-cut has penetrated 7 ft. of ore, assaying 7% copper and \$2.50 per ton in gold and silver. The hanging wall has not been reached.——The leases of the Ottawa mine have shipped 26 tons of concentrate to the Trail smelter. L. H. Biggar, one of the lessees and manager, states that the concentrate was obtained from 700 tons of ore from the old waste

dumps, which averaged 12 oz. of silver per ton. The ore is a dry silver ore. The concentrate contained 75% of the silver in the ore, and the cost of handling, concentrating, and shipping to the smelter was about \$2 per ton of ore treated.

Trail.—During the first week in November, 10,307 tons of ore was received at the smelter. This is believed to be the largest tonnage received during any single week. The following mines contributed: Consolidated company's mines, 10,023 tons; Horn Silver, Similkameen, 43; Jessie Bluebird, Woodberry, 21; Grant, Woodberry, 2; Molly Hughes, New Denver, 27; Ottawa, Slocan, 26; Queen Bess, Almo, 33; Rambler-Cariboo, Rambler, 32; and Violet, Woodberry, 4. It is understood that the stock of lead at the smelter is now reduced to normal, while the surplus of spelter has been much reduced. It is likely, therefore, that the lead and zinc plants will be operated nearly at capacity until the end of the year. Only a comparatively small amount of copper is being refined, there being little ore or concentrate offered for sale.

Vancouver.—The Granby Con. M. S. & P. Co. has entered suit in the Supreme Court against the attorney-general of British Columbia. The plaintiff seeks for a declaration of its rights and liabilities under the British Columbia Taxation Act and for a declaration to the effect that taxes for which it is liable are not due until January 2, 1922, and do not become delinquent until December 31, 1922.

MEXICO

El Tigre.—The owners of the El Temblor are planning to re-open the mine and have sent Tom Frasier, of Patagonia, Arizona, to make a preliminary report on the condition of the property. A great deal of rich gold-silver ore has been taken out since the mine was shut-down, but so much water was developed that further operations were impossible.

Moctezuma.—O. L. Neer and sons are prospecting the Cerro Gordo property south-west of here; they are reported to have found ore. This mine was a bonanza before the revolution, and since then considerable high-grade has been extracted. Several hundred feet of new development has been necessary in order to put the mine in position to ship. The ore carries about 500 oz. silver and some lead and copper.

Nacozari.—A lively contest took place at the Cumpas Mining Agency when the old Good Enough property was thrown open for denouncement. This mine, which is about 12 miles east of here, has had several pockets of very rich gold ore. Smith & Whitehead, of Douglas, won the claim over five other contestants in the lottery that decided the ownership.——Crawford and Odell, of Ray, Arizona, have taken a lease and option on the Pinito mine recently denounced by George Bartlett and others. They expect to build a cyanide plant.

Torreón.—The re-opening of the smelters in this vicinity has caused renewed activities in the famous Sierra de Ramirez, near Symon station, about 90 miles south of Torreón. The formation of this mountain is pure limestone and the minerals are found in blanket-veins which have produced some big bonanzas of silver-lead ore, easily treated. Up to the present time they have been superficially developed by adits. No vertical shafts have been sunk to any great depth in order to ascertain the contents of the lower stratum. It is generally believed that rich orebodies will be discovered by sinking. The mines contain no water, and there will be no necessity for pumps.

There is a good wagon-road from Symons station to the mountain. It costs about P3.50 per ton to freight the ores from the mines to this or other near stations on the National Railways main line. An automobile makes the trip in about thirty minutes over a good hard road. The miners in this district receive from P1 to P1.25 per day. The principal mines are Calaverita, San Pedro, San Agus-

tin, La Bola, Santa Teresa, Providencia, La Blanca, Las Animas, La Humidad, La Esmeralda, La Florida, California, San Andres, Plateros, El Patrocinio, San Pablo, Cristales, San Rafael, and San Jaime.

ONTARIO

Gauthier Township.—A discovery considered important has been made on a location between the Bldgood at Kirkland Lake and the Argonaut in the Beaver House Lake district. The vein is about 3 ft. wide and shows a high proportion of iron and copper sulphides and some visible gold.

Kirkland Lake.—The Wright-Hargreaves has declared a dividend of 5% to be paid January 1 to shareholders of record December 17. It is stated that the dividend, which calls for a distribution of \$125,000, is from the surplus earnings since January 1 last.—Work is progressing favorably on the Queen-Label, where stripping and trenching have disclosed several promising veins. Vein No. 1 has been uncovered for 800 ft. and shows a width of 4 ft. with gold content of \$20 per ton. A. C. Stevens is in charge.

Lightning River.—At the annual meeting of the Lightning River Gold Mines, W. J. Lucy, president, stated that 12 veins had been trenched and stripped, giving evidence of ore. The directors have decided to proceed with the sinking of a shaft.

Porcupine.—An estimate of the gold production of Porcupine and Kirkland Lake, based on the operations of the last two months, places the total at \$1,584,000 per month, or at the rate of about \$19,000,000 per year. The list, comprising seven producing mines, is headed by the Hollinger Consolidated, with a monthly tonnage of 110,000 tons of ore, of the value of \$1,000,000, the Dome Mines coming second, with a tonnage of 32,000 tons, valued at \$240,000. There are approximately 2600 men employed in the producing mines of the Porcupine district and 500 in the Kirkland Lake area. These figures do not include properties in the development stage, which furnish employment to between 300 and 400 men.

A dispute has arisen between the Northern Canada Power Co. and the managers of the leading mines. The company has offered to proceed with further development to satisfy the increase in the requirements of the mines anticipated from projected expansions, provided the mining companies will state clearly what their additional needs will be, and agree to take such increased amounts of power. The Hollinger Consolidated and the McIntyre, however, having intimated that they may proceed to develop power on their own account, the Power company is not disposed to take further action looking to an increase in the supply until some definite understanding is arrived at.

South Lorrain.—The Keeley during October produced 102,819 oz. of silver. Since milling operations were commenced in June the total production amounts to 263,000 oz. No. 6 vein, which has been drifted on for 32 ft. at the 418-ft. level, shows high-grade ore averaging 4000 oz. per ton over a width of 12 inches.

YUKON TERRITORY

Dawson.—Development work is to continue all winter on a number of the properties at Mayo. Electric drills are to be used throughout the closed season on the properties of the Yukon Gold Co., and the Bradley interests, associated with the Alaska Treadwell Co., will continue prospecting at their new camp, Keno Hill. Two shafts, 300 ft. deep, are to be sunk and connected on four levels. The Yukon Gold Co. is opening a vein of galena. The ore is high-grade, said to average well above 200 oz. silver per ton. Sixty additional claims have been staked within a month on Galena hill, where recent promising finds are reported. The winter work of hauling ore from Keno Hill to Mayo Landing for summer shipment down the river is now under way.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

- John A. Burgess is at Carter, Nevada.
 J. Parke Channing was at Miami early this month.
 A. H. Means is at Pine Knot, San Bernardino county.
 Joseph Errington has returned to Oakland from British Columbia.
 J. C. Buchen, formerly at Miami, Arizona, is at Oakland, California.
 Dwight L. Sawyer, recently at Sneffels, Colorado, is at Salt Lake City.
 Horace V. Winchell has been spending some time in Utah on professional work.
 W. Earl Dunn is now with the Midway Petroleum Co., at Montebello, California.
 C. B. Lakenan visited Salt Lake City recently, and then came to San Francisco.
 Arthur Thacher is attending the meeting of the Denver section of the Institute.
 T. Bessler, recently at Sumpter, Oregon, is now at Downville, California.
 A. M. Chamberlain is at Mina La Constancia, Amori, Colombia, South America.
 J. Raick, of Belgium, was recently at Anaconda, Montana, and is now at Kellogg, Idaho.
 W. G. Anderson, recently at the Dolores mine, Chihuahua, Mexico, is now at Stockton, California.
 Roy H. Elliott has been inspecting gravel deposits near Martinsville, in Trinity county, California.
 I. M. Wheeler, formerly general superintendent of the smelter at Great Falls, is now at Liege, Belgium.
 H. L. Tedrow, formerly with the Metates Mining Co. at Mazatlan, Sinaloa, Mexico, is now at Los Angeles.
 Wilbur H. Grant has been engaged on geological work in the Idaho Maryland mine at Grass Valley, California.
 Henry F. Crittenden, of Salt Lake City, has accepted a position on the editorial staff of the 'Tonopah Mining Reporter'.
 Kuno B. Heberlein, formerly general manager for the Peñoles Mining Co., of Mexico, has opened an office at 42 Broadway, New York.
 C. H. Brandes, formerly chief mechanical engineer and general purchasing agent for the American Metal Co., has opened an office at 42 Broadway, New York.
 Walter L. Reid, who has been superintendent of the cyanide plant of the Smuggler Union company at Telluride, Colorado, is now with the United Comstock Mines Co., at Gold Hill, Nevada.

Andrew Rocca died at Calistoga, California, on November 14. He was born at Genoa, Italy, on October 8, 1838, and on his fifteenth birthday sailed for California, landing in San Francisco in January 1854. He went to Bear valley, Mariposa county, and engaged in placer mining, which he followed from 1860 to 1867. In 1869 he became superintendent of the Golden Rock Water Co. In June 1876 he went to Spring creek, two miles from Shasta, and built eight miles of ditches and flumes. He then installed two six-inch hydraulic giants and began operations. In six weeks the debris filled the Sacramento river to such an extent that operations were suspended, and Rocca came to San Francisco. In the same year he became superintendent of the Great Western Quicksilver Mining Co. About 1900 he bought the American quicksilver mine, which he managed until a short time ago, when he was obliged to give up active work on account of his health.

THE METAL MARKET

METAL PRICES

San Francisco, November 22

Aluminum dust, cents per pound.....	65
Aluminum sheets, cents per pound.....	60
Antimony, cents per pound.....	00
Copper, electrolytic, cents per pound.....	13.50
Lead, pig, cents per pound.....	4.95-5.95
Platinum, pure, per ounce.....	\$80
Platinum, 10% iridium, per ounce.....	\$92
Zinc, slab, cents per pound.....	6.75-7.75
Zinc dust, cents per pound.....	9.00-9.50

EASTERN METAL MARKET

(By wire from New York)

November 21.—Copper is active and higher. Lead is quiet and firm. Zinc is dull and easy.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

GOLD POSITION OF THE UNITED STATES

It seems an anomaly that 22 United States senators should urge the passage of a bill providing a bonus for newly-mined gold when the United States has the largest gold monetary stock in its history, as well as the largest in the world. The purpose of the bill, is, of course, to assist the gold mining industry, hard hit by rising costs of operation. These same factors which worked to depress gold mining in this country, increased cost of labor and materials as against a fixed price for gold, also served to curtail gold mining in other countries, but there is an offsetting factor affecting mines in foreign countries which has to some extent afforded relief. That is the foreign exchange situation, says a dispatch in the 'Boston News Bureau'.

With the American dollar commanding a premium, American bankers have been able to buy the world's gold production at a 'premium' as measured in the money of the seller. This situation has helped to maintain production of gold in mines outside of the United States, as the premium realized on sale of gold has tended to offset increase in cost of operations.

The following table shows the world's production, the production in the United States, and the proportion from the United States for each year since 1910.

	Gold production in the world	Gold production in the United States	Proportion produced by United States
1920	\$338,000,000	\$31,186,900	15.1
1919	365,166,077	60,333,400	16.5
1918	383,605,552	68,646,700	17.9
1917	419,422,100	83,750,700	19.9
1916	444,176,500	92,590,300	20.8
1915	468,724,918	101,035,700	21.5
1914	439,078,260	94,531,800	21.5
1913	459,939,900	88,884,400	19.3
1912	466,136,100	93,451,500	20.0
1911	461,980,500	96,890,000	20.9
1910	455,239,100	96,269,100	21.1

Notwithstanding decrease in output the gold stock of the United States has been steadily rising the past year, due to large shipments in connection with settlement of trade balances and foreign debts. Stock of gold in the United States on October 1, according to estimates of Director of the Mint, was \$3,453,008,914, a new high record to date. The stock of gold in the United States on various dates follows:

Oct. 1, 1921.....	\$3,453,008,914	Jan. 1, 1915.....	\$1,815,976,319
Jan. 1, 1920.....	2,784,834,427	" 1914.....	1,924,380,506
" 1919.....	2,787,714,300	" 1913.....	1,878,577,122
" 1918.....	3,080,510,001	" 1912.....	1,797,000,916
" 1917.....	3,040,439,443	" 1911.....	1,708,828,297
" 1916.....	2,864,841,650	" 1910.....	1,638,108,821
" 1915.....	2,312,444,489		

MONEY AND EXCHANGE

Foreign quotations on November 22 are as follows:

Sterling, dollars:	Cable	3.08 1/2
	Demand	3.09
Franc, cents:	Cable	7.15
	Demand	7.17
Lira, cents:		4.15
Mark, cents:		0.37

Eastern Metal Market

New York, November 16.

A holiday on Tuesday, election day, and another on Friday, Armistice Day, have interfered with the usual course of the market, but the tone of all of them is good and business is active in some.

Buying of copper is of considerable proportions and prices have advanced.

Demand for tin is fair but spasmodic.

The lead market continues moderately active and firm.

Quietness pervades the zinc market with values steady.

IRON AND STEEL

Features of the week having a direct bearing on the iron and steel market have been a slowing-down of buying and an easing-off in prices, with some reductions in mill-operations. The remaining six weeks of the year, it is evident, will make a better showing in mill-output than in new business put on the books. Buying of cars is still the most promising factor in the new business.

The composite prepared by 'The Iron Age' for finished steel, now at 2.113c. per pound, is 25% above the average for the ten years before the War. The pig-iron composite price has diminished to \$19.81 per ton. Unlike the price of steel, which has been gradually descending since July 1920, the pig-iron composite reached a minimum in the middle of August at \$18.51, but rose again to \$20.10 in September, with a subsequent downward change of only 29c. in the seven weeks.

COPPER

The market is more active and higher and its strength seems to be augmented slightly every day or two. Values are from $\frac{1}{2}$ to $\frac{3}{4}$ c. higher than a week ago with electrolytic quoted for early delivery (30 days) at a minimum of 13c., refinery, or 13.25c., deferred, with the prospect of this disappearing any day. Some large sellers are quoting not less than 13.37 $\frac{1}{2}$ c., delivered, and some not quoting, having sold as much as they desire at present. Inquiries are numerous for first quarter with some sellers asking not less than 13.50c., delivered, and others higher. Sales for foreign consumption are good with as high as 13.37 $\frac{1}{2}$ c. f.a.s. obtained for some lots. England, Germany, and the Far East are buyers. Japan is reported to be inquiring for 1000 tons. Statistically the market is stronger than in many weeks. It appears that deliveries into consumption in October are now placed at 110,000,000 lb., which is about 40,000,000 more than the monthly average up to that time. With sales last month at 140,000,000 lb. and production not over 40,000,000 lb. per month, the statistical position is regarded as strong. One seller looks for 15c. copper this year, but admits it would not be good for the market.

TIN

The market is only moderately active, sales having been confined to one day the past week. On Thursday, November 10, late in the day, a buying movement started which resulted in the sale of at least 300 tons of Straits tin. About two-thirds of this went to consumers; the positions involved were actual spot and future deliveries, the intermediate being neglected as in the recent weeks. The buying movement started with an inquiry from the interior for 100 tons for actual spot delivery and then other buyers appeared. Yesterday and today demand was inconsequential. Spot Straits, New York, was quoted yesterday at 28.50c., New York. Prices have hovered between 28 and 29c. the past week, due largely to the high value of the pound sterling. Arrivals thus far this month have been 1505 tons with 3475 tons reported afloat.

LEAD

The principal item of news bearing on the market's future course is the announcement that freight-rates from East St. Louis to the seaboard will be reduced from 49c. per 100 lb. to about 35c. on or about December 10. This will enable Western producers to more easily compete in the Eastern market. Demand continues steady at prevailing quotations of 4.70c., New York, or 4.35 to 4.40c., St. Louis. The leading interest continues to quote 4.70c., both New York and St. Louis.

ZINC

The same thing applies to zinc as to lead in regard to a reduction in freight-rates, as explained in the preceding paragraph. The reduction and other conditions are understood to be identical for zinc as for lead, though no official announcement has been made. Buying has slackened until the market is exceedingly dull. The market for prime Western is quotable at 4.70 to 4.75c., St. Louis, with the amount of metal available below 4.75c. very small. Consumers bought well in October covering most of their requirements for a while and producers are not eager sellers, having sold well into their November output last month.

ANTIMONY

In an inactive market quotations have eased to 4.65c., New York, duty paid, for wholesale lots for early delivery with jobbing lots $\frac{1}{2}$ to $\frac{1}{4}$ c. higher.

ALUMINUM

Although the quotation of the leading producer of virgin metal, 98 to 99% pure, continues at 24.50c. per pound f.o.b. plant, for wholesale lots for early delivery, it is believed that it is meeting importers' quotations for the same grade at 17 to 18c., New York, duty paid.

ORES

Tungsten: Conditions are unchanged, the market remaining dull and featureless. Quotations are nominal at \$2.50 per unit upward, depending on grade of ore and other specifications. One seller reports the sale of a small lot at \$3 per unit.

Molybdenum: In an inactive market quotations continue nominal at around 45 to 50c. per pound of MoS₂ in regular concentrates.

Manganese: The condition in this market is illustrated by the fact that one seller cannot get a bid from a consumer on a quantity of foreign ore for shipment from the East. Quotations are nominal at 20c. per unit, seaboard.

Chrome: No demand is reported and quotations are nominal at \$20 to \$26 per net ton, c.i.f. Atlantic seaboard, for foreign ores of standard quality. Rhodesian ore is quoted at \$22 per ton, Atlantic seaboard, for prompt shipment.

FERRO-ALLOYS

Ferro-manganese: No sales or inquiry are reported, except that the Steel Corporation is understood to have sold recently 1200 tons at around \$60, Pittsburgh.

Spiegeleisen: Outside of inquiries for a few carload lots the market is inactive at \$25 to \$26, furnace, for the 20% grade.

Ferro-tungsten: Inactivity is reported with quotations unchanged and nominal at 40 to 45c. per pound of contained tungsten in the domestic alloy and at 50c., duty paid, seaboard, for the foreign.

Ferro-silicon: The 50% alloy is a little firmer at \$58 to \$60, delivered, with a moderate inquiry reported.

Ferro-chromium: Standard alloy is quoted all the way from 10 to 14c. per pound of contained chromium.

Book Reviews

Editorials and Editorial-Writing. By Robert W. Neal. 398 pp. Published by the Home Correspondence School, Inc., at Springfield, Massachusetts. Price, \$3.

This is a compendium of representative writings from the editorial columns of the daily press and the leading weekly journals, together with a small measure of comment by Mr. Neal. At the end of each collection of editorials of a given kind are 'exercises', in the shape of questions that a student is supposed to answer. As a student of a fascinating subject—that of editorial writing—I have read the book with keen interest. The excerpts do not provoke much curiosity or interest, because the average editorial depends for its value chiefly on timeliness; many of them are typical of the poor style that characterizes the average periodical; some of them are so poor as to be excused only on account of the compiler's desire to make his compilation thoroughly representative. The part of the book that caught my attention was Chapter I of Part III, in which 'Ideals, Sidelights, and Hints' are recorded in the form of quotations from the utterances of notable editors and sundry publishers. Here again there is a curious jumble, for Thomas Carlyle and Oswald Villard are found in juxtaposition; likewise Calvin Coolidge and John A. Hill. Reference is made to the passing of the era of intensely personal journalism, typified by Greeley and Watterson, and with it the over-emphasis on partisan politics. Time was when 90% of the editorial space was given to party politics of a narrow-minded type. The lowest point reached by the editorial page was at the beginning of the century; after the year 1900 it improved by being made less personal. H. W. Brundige, a Los Angeles editor, says: "On the whole the editorial page of the present is less mercenary, less partisan, less abusive than that of a generation ago". The Great War helped to improve the status of the editorial page, which attracted increased attention from the readers because the information given by the editors on the economic and political crises growing out of the War were interesting, and when the United States joined the Allies the readers became more thoughtful, so that they paid closer attention to the great issues of the day. Charles H. O'Neill, of Walla Walla, says: "The editorial page of a newspaper is pregnant with a greater responsibility and is a more potent force for good or evil than are the news columns, and, in my opinion, is one of the greatest forces for good or evil in the world". One of the functions of the editorial is to give words to the reader's thought, says James D. Symon, of London. The plain man likes to have his ideas put into fine phrases for him, and when he reads an editorial that is to his taste he slaps his knee and exclaims, "That's exactly what I've been thinking all along". Tom Dillon, of Seattle, remarks: "An editor may prefer being right to being popular, or he may prefer being popular to being right. Of the two it is easier to be popular, and in the majority of cases it is more profitable". As to the control, H. N. Rickey, of the Scripps agency, says: "Our experience has taught us that there is just one way to get and hold the confidence of enough readers to make our newspapers successful. This is for the editorial end to control". These are brave words. Frank S. Baker, of Tacoma, is of the opinion that "the editorial viewpoint is nine-tenths of the newspaper. There was a period in the history of American journalism when the expression of any such belief would have been out of joint with the times, if not unwarranted. Nevertheless, the importance of the editorial viewpoint persisted, and once more the editorial is re-asserting itself, coming again into its own". This is confirmed by A. C. Broughton, of St. Louis, who asserts that "the only good way to sell advertising now is through the editorial page. An editor must know of what he speaks. Con-

fidence in his paper follows, and public confidence in a newspaper gives it its greatest value as an advertising medium". To this H. F. McDougal, of Marysville, Missouri, adds: "If you don't have good editing you can't have a good business proposition". The late John A. Hill advocated a "soul department"; our mealy-mouthed gentleman of 'The Nation' asserts that "no commercial returns, however great, can compare with the moral satisfaction attained by the editor whose lance is ever ready for the public enemy, however armored". How about the national enemy during the War, Mr. Villard? These citations, brief as they are, will weary the reader, I fear, as the originals, of greater length, wearied me. However, some true notes are struck, as by Joseph Blethen, of the Seattle 'Times'; he says: "A paper which would suppress news or deceive its readers at the command of any advertiser, or group of advertisers, would speedily become a hand-bill". It is the publisher's business to take the advertiser's money and therewith secure the best editorial talent with a view to causing the paper to be read, and thereby giving the advertiser a good medium of publicity. "It is the business of an editorial writer", says Osman C. Hooper, of Ohio, "to make himself read, and it may be set down at once that if he is not read, he is a failure . . . To knowledge and spirit he must add a certain literary skill. He must have the ability to present a matter in attractive guise, for it is no less the business of the editorial than it is of the news story to be interesting". As to the style, Dante Barton, of the 'Kansas City Star', says: "The problem of newspaper editorial English is, to preserve a good style and yet reach the large class of persons who do not consciously go in for style . . . The great mass of newspaper readers do, consciously or unconsciously, like a literary quality in their editorial pages". In regard to signed editorials, James M. Lee, formerly of 'Judge', says: "The man who writes the editorial frequently accepts ideas from every member of the staff in his presentation of the subject, and he would be guilty of plagiarism if he should attach his name to the editorial. The editorial 'we' is the real author of the editorial". Indeed, the members of the staff should collaborate so that the writing of any one of them gains from the information and criticism contributed by others. That is the meaning of the pontifical 'we'. One more quotation: Frank S. Baker, of Tacoma, says that a newspaper is "a public trust". That, it seems to us, is the best saying in this compendium.—T. A. R.

Chemistry and Civilization. By Allerton S. Cushman. 151 pp., ill. Richard G. Badger, Boston. For sale by the 'Mining and Scientific Press'. Price, \$2.50.

The contents of this book formed a series of lectures that were delivered at the Wagner Free Institute of Science, at Philadelphia. The author, who is well known for his work on the rusting of iron and steel, as well as in connection with potash fertilizers, is a director of the Institute of Industrial Research. The book is divided into six sections. In the first, the author deals with cosmic chemistry, the formation of the world in its present state, and the evolution of organic life. The connection between modern industry and primordial life is described, leading up to the work of the alchemists. A particularly interesting feature of the section is the study of the phlogistonists—Priestly, Stahl, Scheele, and Cavendish. The influence of the American and French revolutions in making chemistry the servant of man, is emphasized; and due regard is paid to the work and investigations of Lavoisier and Dalton. A notable attraction of the book is the historical description of chemical progress during the 18th and 19th centuries, coupled as it was with the work of Benjamin Thompson, Humphrey Davy, Cavendish, Faraday, and Liebig; and influenced, as it also was, by the foundation of associations of learned men, such as the

Royal Institution of Great Britain and the Royal Society. Subsequent sections deal more directly with the connection between chemistry and modern commercial effort. Improvement in the alkali, and iron and steel industries are described, and attention is paid to ceramics, and the manufacture of portland cement, benzine, coal-tar, and medicinals, as well as to products that can be made synthetically, such as indigo, camphor, and rubber. The concluding sections deal with the subjects of chemistry and the War, radium, and the modern features of chemical achievement, including a study of colloids, the liquefaction of gases, the story of helium, the 'cracking' of petroleum, and the promise of the future as compared with the achievement of the past.

Hayes' Handbook for Field Geologists. Third edition by Sidney Paige. 166 pp., ill. John Wiley & Sons, New York. For sale by the 'Mining and Scientific Press'. Price, \$2.50.

In 1898 a 'Handbook for Field Geologists' was published for distribution to members of the U. S. Geological Survey. Requests for copies of the book came from so many persons outside that organization that the first edition of this work, by C. W. Hayes, who was then Chief Geologist, was prepared. The Survey Handbook was used in the preparation, only those instructions that applied to members of the government survey having been omitted. The present edition, the third, has been prepared in response to a continued demand for a handbook on general geologic practice; the author of the revised treatise is the geologist in charge of the division of geology of the Survey. No alterations have been made in the fundamental plan of the book, although some minor rearrangements have been effected. A brief mineralogy, prepared by Dr. E. S. Larsen, has been added. Methods of geologic work with the plane-table have been revised, and certain recently developed tables for useful calculation in stratigraphy have been added. Some of the schedules have been revised in accord with developments of the science. The contents are as follows: Part I. General practice. Prerequisites for a field geologist. Classification of geologic surveys. Relations to the public. Preparation for field work. Field outfit. Field observations. Estimates of distance. Horizontal measurements. Angular measurements. Vertical measurements. Determination of thickness of beds. Determination of depth of beds. Determination of faults. Form of outcrop. Tables and formulas. Written notes. Map notes. Graphic notes. Traverse notes. Plane-table notes. Profile notes. Land classification surveys. Mine surveys. Collections. Chemical analyses. Geological nomenclature. Part II. Instructions for special investigations. Purpose of schedules. Description and interpretation of land forms. Petrologic observations. Igneous rocks. Sedimentary rocks. Metamorphic rocks. Structural geology. Glaciers and glacial deposits. Investigation of metalliferous deposits. Appendix.

Analytical Chemistry. Vol. I. Qualitative Analysis. By F. P. Treadwell and W. T. Hall. xvii + 597 pp., ill. John Wiley & Sons, New York. For sale by the 'Mining and Scientific Press'. Price, \$4.50.

This is the fifth English edition of a text in German that was written by an American who taught for many years at Zurich. The first edition appeared as an English translation by one who had been teaching analytical chemistry for only three years at the time. Since the fourth English edition was published, the sales of the book have almost doubled, and this has encouraged the making of further alterations. The general treatment has been maintained. The tests for the rarer elements and for the less common acids have been amplified, new reactions being given for nearly every element. The schemes of systematic analysis

have been changed in some places, and new procedures have been introduced. The International Atomic Weights for 1921 have been included. The contents are as follows: Part I. General Principles. Part II. Reactions of the metals: Group V. Alkalies; Group IV. Alkaline earths; Group III. Group II; Group I. Part III. Reactions of the acid constituents. Division of the acids into seven groups. Part IV. Systematic analysis. Part V. Reactions of some of the rarer metals.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

A SIGNIFICANT COINCIDENCE

The Nordberg Manufacturing Co., of Milwaukee, has issued a unique publication called 'Nordberg and the Mining Industry'. The title page is captioned 'A Significant Coincidence'; it says:

About a year ago the 'Mining and Scientific Press' issued a booklet to show the buying influence of some of its subscribers. Two hundred and fourteen of them control the destinies of twenty mines whose aggregate capitalization is more than \$400,000,000.

Of the twenty mining properties illustrated in the booklet,

ing industry could be desired—seventeen out of twenty leading mines selected by a disinterested party? Truly a significant coincidence.

CRAWLING-TRACTOR CRANE

The type BC 'Industrial' crawling-tractor crane, illustrated in the accompanying photograph, manufactured by the Industrial Works, Bay City, Michigan, has been developed to meet the need for a full-revolving tractor crane which can be operated independently of rails. The crane is built in two types—the type BC, with a capacity of 20,000

Bay City Crawling-Tractor Crane

seventeen of them are large users of Nordberg apparatus. When it is realized that the twenty mining companies were selected only with the idea of showing the kind of men who read the publication, the significance of the fact that seventeen of the mines use Nordberg apparatus, is at once apparent.

Fifteen of the twenty plates used in printing the booklet were borrowed from the publisher and are reproduced on the following pages. The list of subscribers has been replaced with short descriptions of the Nordberg apparatus used in the mines illustrated. Two of the seventeen plates have been omitted—one, the plate showing the Braden Copper Co. property, and two, the plate of the Montezuma Copper Co. property. The latter company is controlled by the Phelps Dodge Corporation and most of the Nordberg apparatus which it uses is mentioned on page 11, together with other Nordberg equipment in the several Phelps Dodge properties.

What better proof of Nordberg's pre-eminence in the min-

ing industry could be desired—seventeen out of twenty leading mines selected by a disinterested party? Truly a significant coincidence.

Operation is by means of an internal-combustion engine, which has the advantage of being always ready for immediate use. When not in operation no fuel is consumed and it is not necessary, as often with a steam-operated machine, to have a licensed engineer as operator. The steering of the crane while propelling is accurately controlled by the

operator, from his position in the revolving upper works, by manipulation of the friction clutches and brakes controlling the motion of each tractor-belt. By means of these clutches and brakes either tractor-belt can be readily and instantly disconnected from the motor while the other belt continues travelling at the normal rate of speed. The disconnected tractor-belt can be held stationary by applying the brake, can be allowed to coast with the brake and clutch both disengaged, or the clutch can be allowed to slip, thus allowing operator to turn as sharp or as wide a corner as he may select. All the clutches, brakes, and lever mechanism for steering are in the revolving upper-works, where they are simpler and much more accessible than when a portion or all of them are on the car-body.

JAW-CRUSHER FRAME OF A NEW TYPE

The use of Blake-type jaw-crushers of increasingly large sizes has led to the design of these machines with sectional frames. The reasons are that the single-piece frame is un-

New Sectional Jaw-Crusher Frame

wieldy, and also that it is difficult to make such a frame that will withstand the great crushing-strains developed in the breaking of large pieces of hard rock. The rigidity of a single-piece casting, particularly at the corners, has always been a source of trouble, excessive strains resulting in a breaking away at one of these points.

In an effort to obviate both of these difficulties the sectional or four-piece frame was developed. Ordinarily the four-piece frame is designed so that the side-frames are grooved and the end-frames mortised into them. Bolts through the end-frames, and secured outside the side-frames, hold the parts together. It is difficult to say definitely which of these alternatives, in so far as breakage is concerned, is the worst. The solid frame is absolutely rigid, and the mortised construction provides a sharp corner in which the slightest flexure of the end-frame develops a crack which soon results in a breakage of the side-frame. To further promote this sort of breakage, the ordinary crushing-strains are not distributed along the central axial plane of the side-frames, but are to one side, or are overbalanced.

This breakage is not unusual, but rather common. The technical press abounds in descriptions of clever methods of repairing broken jaw-crusher frames, and promoters of various methods of welding have advertised examples of repairs made on machines of this type. The difficulty has been general, among all manufacturers; it is the result of faulty design. This cannot be cured except through a correction of design, excluding the features that have been definitely shown to be faulty.

Recognizing the basic error of existing designs of this kind, the engineers of the Kennedy-Van Saun Mfg. & Eng. Corporation set about the development of a new type of crusher-frame that would get away from this 'corner' weakness and make a particularly strong point out of what has always been a particularly weak one. The result is the Kennedy hinge-joint frame. In this machine the extremities of the side- and end-frames are made circular in section, the end-frames fitting into the side-frames, the whole joined by a heavy steel pin. In this design the crushing-strains are balanced through the side-frames, taking advantage of all the strength of the metal. Being made of box-section steel castings, they will resist any strain placed upon them in normal crushing operations. There are no corners or edges, and any slight flexure of the end-frames under heavy crushing has no effect whatever on the side-frames, since the pin allows enough freedom to relieve any such movement without transmitting it to the side-frames.

Rigidity of the essential parts of the frame, to maintain shaft alignment throughout, is ensured by three precautions: First, the front end-frame is inclined and the rear end-frame is vertical. Second, heavy through-bolts, with spacers, join the side-frames between the swing-jaw and pitman. Third, the rear end-frame is made with a heavy rib projecting inwardly and securely bolted at its extremities to the side-frames. There is no possibility of the machine getting out of alignment. The inclination of the front end-frame, about the same as the swing-jaw, also ensures half of the weight of the stone being carried on the frame, increasing the sliding movement with less power. This equalizing the slope also has the advantage of allowing the machine to handle effectively a larger piece than would be possible in crushers of the same size that have one of the two jaws vertical.

The remaining parts of the machine are made in the same way that has for years been typical of Kennedy crushers. The spring-balanced pitman, water-jacketed in the large sizes; the efficient lubrication methods; the general rugged strength of the machine are all retained. The jaw-plates are made so that they may be used in either jaw and may be reversed end for end and side for side, an exclusive Kennedy feature, patented, providing twice the wear obtainable from any crusher jaw-plate not so designed.

POWER-TRANSFORMERS

The economical transmission and distribution of electrical energy has largely been made possible through the development of the power-transformer. As the demand for electric power increased, the feasibility of utilizing hitherto wasted water-power and also the economy in supplying power from a single central station became apparent. The location and requirements of the large industrial centres were such that in only a few sections of the country was it possible to take advantage of these economies. The perfection of the high-voltage power-transformer, however, made possible the economical transmission of power over long distances and its

distribution over large areas. There has been a steady increase in the size of power-transformers, and, with the growth of the large transmission systems, voltages which a few years ago were considered impracticable are now generally employed.

The Allis-Chalmers Manufacturing Co. has had no inconsiderable part in this development, having designed and built some of the first as well as a number of the large transformers for the highest transmission voltages used at the present time; it is prepared to build transformers of any capacity for any voltage that may be required. Allis-Chalmers transformers of all sizes are in service on many of the largest transmission and distributing systems of the country.

In general all oil-immersed transformers have the same general characteristics. That is, coils are so assembled that the oil can flow freely through all parts of the transformer, carrying away the heat and preventing hot spots. Natural circulation then carries the hot oil into contact with surfaces cooled either by water or by the outside air; or the oil may be carried by forced circulation to some outside point to be cooled in the same way. In Allis-Chalmers transformers the coils are circular, to give the greatest resistance to distortion on short circuit, and are usually pan-cake type, with short paths for flow of heat to the oil, which circulates through vertical ducts. This gives a good circulation in the oil, which flows upward past vertical coil surfaces. A thin light oil is used which flows readily and which at the same time has absolutely safe flash- and fire-temperatures. Single-phase transformers are shell-type. Therefore the coils are assembled on one leg and are placed centrally in a round tank. Thus no oblong tanks are used except for the three-phase transformers built with phases placed horizontally. Tanks used are of boiler-plate with welded seams and are either plain, jacketed, or arranged for bolting on radiators, as in the large self-cooled units.

LITIGATION OVER PATENTS

A suit has recently been brought by the Chicago Pneumatic Tool Co. in the United States District Court in the Western District of Michigan against the Keller Pneumatic Tool Co. for injunction and accounting of profits and damages due to the alleged infringement of certain United States patents by the manufacture and sale of the so-called Keller Master Super-Hammer. The patents involved are No. 879,106, 897,958, 1,029,082, and 1,126,069.

Suit has also been brought against the H. Channon Co. in the United States District Court at Chicago for infringement by the sale and offering for sale of the above-mentioned Keller hammers, and for unfair competition by acts calculated to produce confusion in the trade.

The above suits should not be confused with the one heretofore brought against the Keller Pneumatic Tool Co. in the United States District Court at Philadelphia for infringement of patents No. 730,887, 822,146, 866,573, and 917,242, which suit is being vigorously prosecuted.

Suit is also pending in the United States District Court at Chicago against the Keller Pneumatic Tool Co. for infringement by the use of the trade-name 'Keller', and certain other trademarks of the Chicago Pneumatic Tool Co. The company desires to warn the trade and public not to make, use, or sell tools or parts thereof which infringe the patents and trade names that belong to them.

COMMERCIAL PARAGRAPHS

Bulletin No. 239, issued by the W. S. Rockwell Co., relates to an improved type of forge-furnace built to meet the demand for equipment which will lower production costs. The novel features of the furnace consist of means for better application of the heat, protection of the operator, and utilization of waste gases to pre-heat air and fuel for

combustion. The comparatively cool working end permits the close grouping of furnace and machine and a more efficient method of handling, resulting in greater output, better working conditions, and decreased cost of production.

The Pawling & Harmschfeger Co. has just issued a new bulletin on the P & H No. 6 radial wall-drill. This drill is designed to meet the demand for a simple and effective machine for drilling, reaming, and countersinking large unwieldy pieces, such as structural shapes and boiler-plates.

H. A. Kimber, formerly of the Quigley Furnace Specialties Co., L. W. Marso, O. M. Itau, formerly consulting engineer to the Philadelphia Rapid Transit Co., and W. O. Rankin have become associated with the Hardinge Co. since the pulverized-fuel department of the Quigley Furnace Specialties Co. has been acquired by the Hardinge Co.

A booklet entitled 'Flotation', which is a brief survey of this subject by H. J. Stander, is being distributed by the Hercules Powder Co. The book contains interesting information on the flotation processes and the various oils used. Mr. Stander, who is also the author of 'The Flotation Process', 'Interfacial Tension in Flotation', etc., is now flotation engineer with the Naval Stores Division of the Hercules Powder Co. The pamphlet is not of an advertising nature, but has been published simply to provide information to users of flotation oils. The functions of oil in flotation are summarized as follows: 1. Decreasing the surface-tension of the water with the result that a more permanent gas bubble is formed. 2. Forming a molecular oil-film around mineral particles in contrast to its action on silica and so producing a surface film that promotes the non-wetting property. 3. Increasing the force of cohesion between sulphides and so helping in the formation of a network of mineral particles. 4. Acting as an emulsifying agent, affecting the gas bubbles in such a manner that a decrease in size and an increase in number become apparent. Anyone interested may obtain a free copy of this booklet by writing to the Naval Stores Division, Hercules Powder Co., Wilmington, Delaware.

The development of the hydraulic turbine in the United States during the last fifteen years has been phenomenal. Prior to this period, American builders were unquestionably outranked by those in Europe. The hydraulic turbine, although built for many years in America, had been developed experimentally with little recourse to theory. European designers, on the contrary, had analyzed the theory of the turbine with great care, and, although somewhat lax in their experimental work, had acquired a decidedly superior knowledge of the art. About the year 1905, however, the development of water-power on a large scale in this country stimulated American turbine builders to a more progressive policy. Since that time the improvements in design have been remarkable; today the turbine builders of the United States lead the world. No other continent has developed its water-power on so large a scale as North America, and the turbines for these mammoth plants are of a size and refinement of design unparalleled in Europe or elsewhere. Thorough tests are made at Holyoke, Massachusetts, which at present is the only official testing flume in the United States; and they have been an important factor in the development of the American turbine to its present state of high efficiency. In this respect the **Wellman-Scaver-Morgan Co.** has been a leader. This company was first to obtain an efficiency of 90% at Holyoke (test No. 1799, efficiency 90.47%); likewise the company was first to obtain an efficiency of 92% (test No. 2497). Since that time runners have been developed to meet practically all ordinary conditions at an efficiency of 90% or over when tested in the Holyoke flume. Under favorable conditions and with vertical settings, results in the field show efficiencies as high as 93%.

T. A. RICKARD, . . . Editor

TO those who see only the surface of things, the appropriation at this particular time of \$1,000,000 for building a concentrator to treat copper ore may not seem sagacious. Nevertheless, the directors of the Britannia Mining & Smelting Company have authorized the expenditure of that sum to build a 2500-ton flotation plant to replace the one destroyed by fire last February. By this action they display confidence in their mine and confidence in the market for copper. They need a new concentrator, and the sooner they build it the sooner can they resume production!

IN this issue we publish a timely article by Messrs. Girard B. Rosenblatt and Graham Bright on 'Electricity in the Development of the Mining Industry'. Both gentlemen are connected with the Westinghouse company, Mr. Rosenblatt being particularly well known throughout the Western States by reason of his position as engineer in the mining division of the industrial department of the Westinghouse organization. His contact with the problems of the mining industry is probably as intimate as that of any other electrical engineer in the country. Some believe mistakenly that there remains little opportunity for further marked progress in the application of electricity to the operation of mining and metallurgical plants; this paper draws attention to the directions in which advance may be expected. The owners of mines should not overlook the necessity for considering all factors in comparing the cost of work done by electrical machinery as against that done by hand or by power in other forms. The first cost of electrical equipment may be high, the unit-cost of electric power may seem excessive, but the comparison should be made on the final cost per unit of accomplishment. The greatest need of the mining industry today is efficient production; the intelligent use of electricity is a means toward that end.

SPEAKING of waste in industry, it is noted that the committee of engineers appointed by the Federated American Engineering Societies made no mention, in its report, of the appalling loss that is incurred because of lack of systematized publicity in the results of research work and technical operations. We stressed this point in a recent editorial on indexing current technical literature, and it has elicited several appreciative comments

from readers. Strangely enough, however, no replies that were sent for publication came from librarians, but we were interested to see, in a recent issue of 'Chemical and Metallurgical Engineering', that Mr. K. C. Walker, the Research Reference Assistant at the Bureau of Mines Experiment Station at Pittsburgh, makes a strong appeal for the special technical library. Andrew Carnegie is quoted as saying that his organization wasted a great deal of money because it failed to find out what others had done before research and experimentation were commenced. A considerable number of the larger industrial organizations in the United States maintain efficient staffs to abstract and to index material that may be of interest or of value to their technologists. In one case, in which about 200 publications are examined, the value of such a department has been proved by a striking increase in the number of inquiries; it is estimated that 32 large commercial firms in the country publish abstract bulletins for the use of their own employees, but small concerns are unable to meet such an expense. A centralized and co-operative effort is desirable, particularly in regard to progress in the mining and metallurgical industries. The waste that occurs as a result of inefficient indexing, of faulty systematizing, and of misguided publicity-efforts may be the natural sequel to an effort to eliminate a fault rather than to prevent its occurrence.

FLOUR GOLD in sea-water is something new. "As you are aware," writes an enterprising individual, "there is gold in the ocean to the amount of 60 cents to every cubic yard . . . The waves of the sea have been throwing up the Flour Gold on the sea shore for ages and ages, till the ground is saturated with it. We have had tests made of the mud and sands along the shore on the Oakland side [of San Francisco bay] and got the same uniform result: \$16, \$25, and up to \$50 per cubic yard. We have started to build a machine that will save this gold, and, owing to the ruinous prices of the machinists of Oakland we have run out of money to finish it." Then comes a harrowing description of past difficulties, of the knavery of a lawyer, of the announcement that the patent papers are on file in Washington, and the intimation that efforts are being made to build the machine "so as to recover the flour gold of which there is more than any other kind of gold". Fresh bait is used afterward to tempt the would-be investor, who learns that the gold

"is washing into the ocean in all parts of the whole world, millions and billions of dollars of it every year". The scheme evidently relies on perpetual motion; for the immense quantity of flour gold that it is the inventor's mission in life to recover is, apparently, washing into the ocean and, simultaneously, being thrown up on the seashore, particularly near Oakland. We believe there is gold in sea-water, but we are sceptical as to the results expected by the use of a machine that, it is claimed, "will save the Flour Gold in the earth, as well as in the waters of the Ocean". To this we may add that the idea of winning gold from the sea originated as early as 1872, when E. Sonstadt, in the 'Chemical News', mentioned qualitative experiments that he had made and stated that the amount of gold was "certainly less than one grain in the ton". He has been misquoted repeatedly, as having said that there was "one grain per ton". As we have said more than once, there is gold in the sea and silver in the moonbeams.

THE residue of today may be a source of supply for tomorrow. Values are of relative significance. A mine that was considered unpayable 50 years ago might be termed a bonanza at the present time; and so it is that discarded residue, which contained so little metal when dumped that the engineers in charge of operations congratulated themselves, often becomes an asset for succeeding generations. The value of an accumulation of such material depends to a great extent on the scheme of treatment adopted by the pioneers. The concentration of gold that is disseminated throughout sand is more feasible than the concentration of gold that is associated with slime. The removal of the valueless or the isolation of the valuable is the basis of all metallurgical processes, so it is evident that the avoidance of sliming will ensure the possibility if not the probability of additional treatment and additional profit. Immense dumps of sand have accumulated on the Witwatersrand goldfield, after many years of operation by an amalgamation-cyanidation process. The average assay-value of the material is exceedingly low, probably under 40 cents per ton, so that a repetition of hydro-metallurgical methods for the further extraction of the gold from the unconcentrated residue may be considered impracticable; but if a cheap method of separation be employed, it is possible that the amount of material to be treated by actual extraction methods of amalgamation or cyanidation, or both, may be reduced considerably, and the cost of such treatment should be diminished proportionately. Many schemes have been proposed, and we note that an attempt is to be made in the near future to treat the tailing that has accumulated from the leaching of the ore from the May Consolidated mine, at Johannesburg. From the scanty information available it would appear that the material is to be pulped with water and subjected to treatment in a special type of hydraulic classifier. The underflow from this is to be passed over tables of the Wilfley type, yielding concentrate, middling, and tailing, the last-mentioned being returned to join the overflow from the reject

of the hydraulic classifiers. It is hinted that amalgamation will be adopted to recover the gold from the concentrate, whereas the middling will be re-ground in tube-mills and, possibly, re-concentrated. The results of the work will be watched with interest by those who are anxious for a revival in gold mining, especially if they have at hand residues from a leaching process.

CONCENTRATION involves the segregation of waste and the isolation of the more valuable constituents of the ore. The selective treatment usually begins in the mine; later, it often forms a preliminary to metallurgical treatment in the mill and cyanide plant. In this issue Mr. C. Flury describes an interesting innovation at a plant in Korea, at which, after the number of stamps in the battery had been increased, it was decided to avoid the overloading of the hydro-metallurgical equipment, the capacity of which was not increased, by concentrating the crushed and milled ore and by discarding some of the waste. A few comments on Mr. Flury's figures are pertinent. Concentration usually involves a loss of the metal that is being sought, and must be taken into account. We do not know the amount of such loss in this particular case; we presume that it was insignificant; under such conditions the procedure of concentration prior to cyanidation is a sensible one. A second point is that, if a high-grade product can be secured, it is advisable on account of the small tonnage to consider the possibility of obtaining a maximum extraction of precious metal. Comparisons of extractions are misleading unless the grade of the material treated be taken into account. If the concentrate be rich in gold that is encased in pyrite, as it often is, sliming and amalgamation are indicated as a suitable preliminary combination treatment, for by such means it is usually possible to ensure low ultimate residual loss. The cyanidation of an amalgamation tailing is invariably highly successful. A fair extraction can be obtained sometimes from high-grade material by the adoption of a leaching process, but it usually involves an abnormal loss of chemicals because of the protracted time of treatment. In Mr. Flury's case the problem is complicated by the presence of graphite in the ore; this is removed with the slime during concentration, thus obviating the danger of re-precipitation of gold during cyanide treatment. An interesting application of this idea of concentration prior to cyanidation is being made in South Africa, where it is proposed that, instead of cyaniding the whole of the sorted ore, the latter after crushing and milling would be subjected to oil-flotation, whereby it is claimed that the amount of material to be treated subsequently by amalgamation and cyanidation may be reduced to one-tenth, the concentrated portion carrying 95% of the gold in the ore. As we pointed out in a recent issue, there is little hope for further improvement on the Witwatersrand by the introduction of a process that aims to increase extraction or to decrease costs per ton if cyanidation or amalgamation, or both, be used. Nevertheless, if the tonnage can be reduced appreciably before wet-

chemical treatment is commenced, it is evident that a field exists for the introduction of efficient concentration apparatus and methods; there is also justification for the adoption of more expensive methods of all-sliming in conjunction with amalgamation, and as a preliminary to cyanidation and the ultimate treatment of the finely-ground pulp on a vacuum- or pressure-filter. Further developments will be watched with interest; in the meantime, Mr. Flury's experiences may well form the basis of further discussion from interested metallurgists.

Concentrating Magnetite Ore

The first unit of a plant that is expected to prove definitely the success of the proposed scheme for concentrating the low-grade magnetite ore of Minnesota is almost completed. For years the Mesabi Range north of Duluth has been the source of 'high-grade' hematite ore containing 55% iron. Of this there remains, according to various estimates, between $1\frac{1}{2}$ and $3\frac{1}{2}$ billion tons; in addition, there is known to exist, in the eastern portion of the range, something like 30 billion tons of material containing magnetite and averaging about 25% iron, that until recently did not even aspire to be 'ore'. Seven years ago Mr. Edward W. Davis, then an instructor in mechanical engineering at the School of Mines of the University of Minnesota, devised, after many experiments, a crude contrivance for the separation of the iron minerals from the worthless portion of this low-grade magnetite ore. In 1915 Mr. W. G. Swart, of Denver, made a visit, first to the iron ranges east of Mesabi, and then to the University at Minneapolis, where he carefully inspected Mr. Davis' machine and listened to his explanation of its operation. The result of this examination was a telegram to Mr. D. C. Jackling, whom Mr. Swart represented, saying: "The whole enterprise of the eastern Mesabi warrants further investigation". The next step was the erection of an experimental plant at Duluth; here Mr. Swart, with the assistance of Mr. Davis, spent three years in improving the machine and satisfying himself that the low-grade ore could be made to yield its magnetite. During the period of the War the plant successfully treated 25% ore, making a concentrate analyzing 65% iron, which, when sintered, formed a most desirable feed for iron blast-furnaces. Mr. Davis, who since 1919 has been superintendent of the Minnesota School of Mines Experiment Station, describes the device, upon which rests the success of the entire project, in these words: "The wet-magnetic separator is similar to the ordinary log-washer in construction, with the exception that to the bottom of the trough is attached a series of magnets. These magnets hold the finely ground magnetite to the bottom of the trough, where the action of the logs forces it up a slope and delivers it as a clean concentrate, while the non-magnetic material is kept in agitation and is washed over the rear end of the machine as tailing. The machine is simple and economical in operation, and the wear on the logs is much less than in ordinary log-washers, owing to the fineness of the particles of ore that are treated, all of it having been

finely ground before going into the machine". The operation of the experimental plant at Duluth had proved conclusively that the machine could make the required separation; it had supplied data on which to base an estimate of the cost of operations on a large scale. This estimate and the others made by Mr. Swart and his assistants were sufficiently satisfactory to warrant the next step in the program of exploiting these low-grade ores. Mr. Swart went north to a station having the euphonious name of Sulphur Siding, and there built an industrial town, which he christened Babbitt; here 375 workmen and their families have made their home, and here during the last two years \$1,000,000 has been spent in erecting and equipping the first unit of the concentrator; in providing the necessary shops, power-plant, and other adjuncts; and in preparing for steam-shovel mining operations. The preliminary work is almost completed; within a few months productive operations will commence, and shortly thereafter the question 'How cheaply can a concentrate analyzing 60% iron be obtained?' will be answered. Will the enterprise be an economic as well as a technical success? Mr. Jackling and his engineers have endeavored to foresee every unfavorable contingency; they have checked and re-checked their calculations and they are convinced that they are right, or they would not have invested \$5,000,000. But even the best of engineers is not infallible. Mr. Jackling spent many millions in an effort to win a profit from the low-grade gold ore of Juneau, in Alaska, but he failed because he erred in estimating one factor of the many involved in his calculations. He mined the 'rock' for less than he had expected; he milled it for less than he had hoped; but each ton contained less gold than he had anticipated—this was 'the nigger in the woodpile'. In the eastern Mesabi project the existence of adequate deposits of ore having the required iron content has been proved as conclusively as is reasonably possible; it is an easier task than sampling the goldbearing rock at Juneau. The ore will be mined by steam-shovels and there is little room for error in estimating the cost. One consideration is the fact that, on account of the weather, open-cut mining can be conducted during only six months of the year; this will be overcome by storing the winter's supply of ore in stock-piles near the mill. In anticipation of the ultimate exhaustion of the high-grade iron ores of the United States the big steel companies have already acquired iron-ore deposits in Spain and Sweden, in Cuba and Brazil, and in China; they can afford to transport ore by boat and to smelt it on the coast in this country, but to transfer it and carry it to the furnaces situated inland is costly. On the other hand, the sintered concentrate enjoys the advantage of cheaper transportation to inland steel plants; as a material for furnaces it is ideal, so that a market seems assured. The one uncertain factor in the project is the cost of treating the ore. It is to be crushed in stages, first through a special heavy jaw-crusher to 12-inch size, then through another jaw-crusher to 5-inch, through gyratories to 2-inch, and in rolls to $\frac{1}{2}$ -inch. This product will pass through a 'drum cobbler'—a belt-conveyor with a magnetized head-pulley

—by means of which half of the crushed material will be discarded. The remainder will be crushed wet in ball-mills to 100-mesh, after which it will pass through the machine devised by Mr. Davis. Coke-breeze, anthracite-dust, or other cheap fuel will be added to the concentrate *before* dewatering, and the mixture will be partly dried on vacuum-drum filters. The cake will be sintered or nodulized before shipment to the blast-furnaces. The narrow margin of profit that is anticipated when the entire plant is in operation is indicated by the fact that the present \$4,000,000 unit is not expected to earn more than enough to cover the cost of operation; a plant of 22 units with a combined daily capacity of 75,000 tons of ore, rendering possible a wider distribution of the overhead cost, will be required to make the venture profitable. Steel is the backbone of industry and it is inevitable that the deposits of the eastern Mesabi should be utilized eventually. Let us hope that the time has arrived.

The Washington Conference

The Conference at Washington continues to occupy the centre of the stage in world affairs, and it is well that it should do so; for the matters that are being considered by the leaders of the nations at our Federal capital are of paramount consequence to humanity. So far the deliberations seem to have progressed satisfactorily. The proposal, made by the United States, for a reduction of navies has been received favorably; and the adjustment of relations between China and the powers interested in the exploitation of that country is making progress. Any attempt to arrive at an international agreement for the reduction of armies has been checked for the moment by the oratorical gesture of the French Premier, and his insistence upon the danger to which his country is subject from German aggression; but it is still to be hoped that such assurances of protection for France may be forthcoming as will justify M. Briand and his fellow delegates in diminishing their military establishment. For the rest, the Conference is providing instruction to all of us; the public discussion of great questions by competent men is educating us in matters of vital concern to the welfare of civilization; the exchange of ideas, even if it provoke an occasional clash, helps to promote mutual understanding between the representatives of the nations on whom at this period of history rests the direction of world affairs. Our own representatives have done credit to themselves and to the United States; Secretary Hughes has demonstrated statesmanship of a high order; and there is reason to believe that his colleagues have shown similar sagacity in committee. Much is being written about the Conference in the daily press, and it is sad to see how much of it is of a petty kind. From Mr. Bryan to Mr. Bill Jones the correspondents think it clever to impute sinister motives and to intimate a knowledge of intrigues that are largely of their own invention. The worst exhibition is that of Bristance, whose articles in the Hearst press exhibit a malignity and ignorance worthy of a vicious schoolboy. It is pitiful to think that many thousands read his piffle

as gospel and have no means of correcting the misinformation with which he fills them. Mr. David Lawrence and Mr. Louis Seibold are among the few gentlemen of the press that appear able to maintain a sane mental poise and endeavor to treat the doings of the Conference with intelligence and philosophic discrimination. They are upholding the best traditions of their craft. This is a time when the press is under heavy responsibility, for upon it rests the duty of furthering the great purpose of the Conference by just comment and the honest transmission of news. To mislead or to misinform at this juncture is a crime against humanity. The issue is too great to excuse levity and too momentous to pardon pettiness of mind. As Mr. Lloyd George has said: "The American Conference has the future of civilization in its charge; it is the greatest event the world has seen in 1900 years". We are proud to have it named the "American" conference, for it was planned by the President and is being led by the Secretary of State. Even if it fail in creating a millenium, it is destined, we believe, to mark the beginning of a new era in world affairs. Although we cannot go as far as Mr. George Harvey in believing that "the night of concealment, deception and intrigue has passed, and the day of openness, frankness, and sincerity has dawned", we do believe that the Conference will demonstrate the need for open discussion of international difficulties, and will induce the governments of the world to appreciate the fact that wars, like labor strikes, can be obviated by means of discussion and delay, by the ventilation of conflicting ideas and the public presentation of the points at issue. The peoples of the earth insist that wars shall not be foisted upon them by the hole-in-the-corner decisions of a military clique or a group of unscrupulous diplomats playing men as if they were mere pawns on the board of destiny. It is certain that if the Serbian question could have been discussed frankly at a conference of the powers and if the facts of the case could have been made public in the summer of 1914, it would have saved the world from the horror of four years of slaughter and devastation; if England had been in a position to state frankly that she would resent by force the invasion of Belgium and if France had made it known that she would fight on the side of Russia, it is extremely unlikely that the Kaiser and his followers would have dared to embroil the world. Another "if": if the United States had known, as we know now, that a world war such as that of 1914-1918 would involve her inevitably, she also would have had something to say. Whether it be a League of Nations or an Association such as the President advocates now, it is certain that there is needed an organization, a deliberative assembly, for the public discussion of international questions. A frank talk has prevented many a fight. Most fighting is caused by misunderstanding either of motives or of consequences. The Conference is a rainbow across a sky from which a bloody rain has but lately fallen upon the homes of men. We cherish the hope that is symbolized by the rainbow, and urge our readers to do what they can, in private and in public, to uphold the hands of our representatives at Washington.

DISCUSSION

Concentration and Cyanidation

The Editor:

Sir—The extension of our mill from 30 to 50 stamps necessitated the installation of concentrating equipment, as the leaching-plant became too small; it was decided to concentrate the sand, after a preliminary classification of the pulp into sand and slime, by means of 10 Wilfley tables, one to each battery. Little time could be spared for preliminary research, and anxiety was expressed as to whether the extraction would remain as before, or become better or worse. It was expected in some quarters that an increase would occur, because the reduction in tonnage would allow a longer time for cyanidation treatment and an increased number of transfers.

Formerly, by direct treatment, the process was applied as follows: To 60 metric tons of sand, mixed with 150 kilogrammes of lime, 8 tons of working solution was pumped. This solution contained 1.8 kg. KCN and 1.4 kg. CaO per ton; it was strengthened with 25 kg. of cyanide at first, which was added as a solid to the charge during pumping, bringing the working strength up to 4 kg. KCN per ton. This strong solution was left in contact with the sand for a period of eight hours. After percolation, the ordinary working solution was applied. Every four days the sand was removed into another vat and finally discharged to the tailing dump. After 12 days total treatment the extraction averaged 80%.

In order to be on the safe side we commenced with the low concentration of 1 to 2. To treat the concentrate with cyanide, the same method was adopted as for ordinary sand, but the time of treatment was extended to 16 days, and instead of transferring twice we removed the concentrate three times. Extraction was as follows: First treatment, 71.1%; second, 74.7%; third, 83.1%; fourth, 86.5%. It seems improbable that an extraction of only 3.6% should be obtained by the second treatment, 8.4% by the third treatment, and only 3.4% by the ultimate treatment. Nevertheless, the actual extraction, indicated by the clean-up, was 86.5%, thus showing an increase in extraction of 6.5%, as compared with direct treatment of sand.

During the second month, under the same conditions in regard to concentration, the extraction was as follows: First treatment, 60%; second, 76.8%; third, 83.3%; fourth, 86.5%. The final extraction was the same as in the preceding month. It is interesting to note that the extraction during the first stages of treatment is 10% higher than is the case when sand is being treated. This must be attributed to the preliminary concentration. With concentrate of varying grade, the higher-grade

material gave, as a rule, the better extraction. For instance, concentrate of an assay-value of \$20.50 gave tailing, \$2.65 and extraction, 87.6%; concentrate with an assay-value of \$15.25 gave tailing, \$2.65, and extraction, 83.5%. With a concentration of 1 to 3 the extraction was as follows: First treatment, 66%; second, 76.5%; third, 81%; fourth, 85%; fifth, 87.5%. I therefore raised the concentration ratio to 1 to 4, as there was still an opening for improvement, and obtained the following results: First treatment, 73%; second, 80.4%; third, 85.5%; fourth, 87.5%; fifth, 88.7%; sixth, 90.2%. The actual extraction amounted to 93%. The higher the concentrate was in value the higher became the extraction. The higher the ratio of concentration the longer became the period of treatment and the more numerous the transfers. When the concentration was 1 to 4, the concentrate remained 25 days under treatment and was removed five times, whereas the ordinary sand was submitted only to 12 days treatment and one transfer. By comparing the treatment of the concentrate with that of the ordinary sand, after each had received an equal time of treatment and the same number of transfers, the results were as follows: Extraction from concentrate, 85.5%; extraction from sand, 80%. The improvement must be credited to concentration. The difference between the maximum extraction in each case, 90.2% and 85.5%, must be attributed to the greater number of transfers and to prolonged treatment.

The improvement in extraction owing to concentration must be due to physical change. The concentrate is cleaner than the original sand, the latter being enveloped in a skin of clay, which I have failed to observe on the concentrate. Such a film is removed by the cleaning action of the water and the shaking movement of the tables. Besides, our ore carries a considerable amount of graphite, which is eliminated by the tables, being washed away in the tailing. In addition to the circumstance that the concentrate is cleaner than the sand, the solution is in more intimate contact, and the elimination of soluble salts on the table-deck results in a considerable saving of zinc, cyanide, and lime. It is impossible to state how much this saving is. The question is complicated; economies are caused by the reduction in tonnage; an increased consumption of chemicals is due to the concentration of the metal in the concentrate; this, however, is not so high as was expected, because the water film on the table-decks removes a great deal of worthless and chemical-consuming material.

When the alkalinity is held at the same amount for the treatment of the concentrate as for the sand, the amount of precipitate increases almost in the exact pro-

portion as the ratio of concentration. For the same amount of gold recovered we had about three times as much precipitate from the 1:3 concentrate as we would have obtained by treating the ordinary sand direct. I decreased the alkalinity to as low as 0.7 kg. CaO per ton of solution. The precipitation remained excellent, showing only traces of gold in the sump, but the amount of precipitate became normal, containing as much as 40% gold and silver, so that eupellation was not warranted. A saving of one-half of the zinc and lime was also effected.

The increased extraction in the leaching-plant when the sand is concentrated before treatment is not due to the increase in the capacity of the plant, which allows longer treatment and more frequent transfers; it must be credited to a large extent to a favorable physical change in the material during the passage over the concentrating tables. To the same cause must be attributed economies of chemicals, which cannot be accounted for by the reduction of tonnage.

Wetting and Amalgamation

The Editor:

Sir—In your issue of November 12, Mr. Samuel H. Dolbear asks for opinions on the view of one of the Examiners of the U. S. Patent Office, namely, "That the selective preference of quicksilver for gold is analagous to the selective preference of oil for metalliferous substances". Mr. Dolbear himself holds opposite views on the subject.

Except that I think "metalliferous substances" is rather too vague and too broad an expression, I am disposed to agree with the Examiner. That mercury possesses the property of 'wetting' gold, while it will not 'wet' the other constituents of ordinary gold ores, seems to me to be its great value as a medium for concentrating the precious metal. The fact that afterward the gold absorbs mercury and forms a series of amalgams of definite and indefinite composition undoubtedly plays a part in the concentration of the gold, in that it cements the particles of gold together and to amalgamated copper, and thus better retains them in the riffles of sluice-boxes and on the plates of stamp-batteries; but, in my opinion, this is altogether a secondary part, and in itself would be quite useless.

When a particle of gold is first ejected from the mortar-box of a stamp-mill onto the outside copper plate it may readily be moved about from one part of the plate to another by pushing it with a finger, but it is not easy to detach it from the plate, is being securely held there by what Professor Vernon Boys in his delightful little book, "Soap Bubbles and the Forces that Govern Them", calls the elastic surface-skin of liquids, the liquid in this case being mercury. The gold at once begins to absorb mercury, and, in the event of a fairly 'dry' plate being used, ultimately becomes firmly cemented to the amalgamated surface of the copper plate.

One may readily demonstrate the selective property of

mercury for 'wetting' and concentrating gold by mixing a few particles of clean gold with some particles of quartz on a large laboratory watch-glass, adding a globule of mercury, and rolling it about by gently rocking the watch-glass. The mercury will readily 'wet' the particles of gold, pick them up, retain them within the 'elastic surface-skin' of the globule, and carry them away from the particles of quartz; that is, if the gold particles are not too heavy. Here, and here only, in my opinion, lies the analogy between the two processes, although I do not know that it has been definitely demonstrated that the oil used in flotation does not sometimes penetrate beyond the surface of the particles of sulphides and that in some instances a certain amount of chemical combination does not take place between the oil and the sulphides.

If I understand him rightly, I disagree with Mr. Dolbear when he says: "Gold amalgam in an excess of quicksilver is either a true solution as an alloy dissolved in quicksilver, as gold in a true solution, or it is an alloy of variable chemical structure, according to the amount of quicksilver available for the structure". Some 25 years ago I made some experiments to discover how much gold mercury was able to dissolve at ordinary temperatures, and the conclusion I reached was that the affinity between the two metals was exhibited more by the precious for the base than the base for the precious metal. In order that the gold might be in a fine state of division, so that the mercury might have every opportunity of dissolving it, it was added to the mercury in the form of a slightly acid solution of the chloride. The gold was readily precipitated from solution by the mercury, of course, and at once amalgamated with it. To give the gold every opportunity of going into solution the mixture was kept at a temperature of 100°C. for several days, it being well known that gold is more soluble in hot than in cold mercury. I closed the end of a piece of half-inch glass tube, about 30 inches long, and drew out a series of horns, about four inches apart, on one side of the tube. This was supported in a burette stand, the mercury and amalgam, while still hot, being poured into it, and allowed to stand for several days, so that solids might have every opportunity to settle. Commencing at the top one, the points of the several horns were nicked by a file, and broken off, thus allowing the mercury above them to flow out of the tube. Each section was collected separately, and assayed for gold. I have not the details at hand, but I remember that the mercury in the upper sections of the tube contained on an average 0.125% of gold. The mercury in the last two sections above the bottom one contained slightly more gold, which I concluded was due to a small amount of amalgam in suspension. This clearly demonstrated, I think, that under the most favorable conditions mercury will not hold in solution more than one-eighth of 1% of gold at normal temperatures, say, about 18°C. The amalgam in the bottom of the tube was transferred to a dish, and the surplus mercury was drained off. The amalgam was then plunged into a porcelain dish containing boiling nitric acid. When all action had ceased

the mercuric nitrate was poured off, the residue being washed first with hot dilute nitric acid and then with hot water; then dried, and annealed in the dish in a muffle. The gold thus obtained was in the form of the most gorgeously beautiful mass of cubic crystals and skeletons of crystals. It was on view in my laboratory, at Halifax, for many years, and was much admired by visitors. The skeleton-crystals would seem to indicate that a definite alloy of gold and mercury had been formed.

Revision of the Mining Law

The Editor:

Sir—Mr. Albion S. Howe, in his contribution on this subject in your issue of November 16, wants to know "if the gentlemen who framed these proposed laws had ever hunted any section corners in remote places". Permit me to reply that one of them did, and that for three years a large portion of his income was derived from the hunting of section and quarter corners, re-establishing them when they were lost, and dividing sections; and he is quite well aware of the difficulties attending this work.

In the law as proposed by the Bureau of Mines it is not vital that the claims be laid out on cardinal lines, or that they conform with the subdivisions of the Public Survey. It simply was meant that the committee thought that these provisions were desirable. If the general feeling is that they are not, the real spirit of the proposed law will not be affected by changing it. Incidentally, it is interesting to note that a great many criticisms of the proposed law are made by people who evidently have not read the law in its entirety, nor have they read the present mining law and they do not know that a great many of the things to which they object are actually in the present law.

New York, November 21.

The Use of Scrapers Underground

The Editor:

Sir—I have read with much interest the able article on 'The Use of Scrapers Underground', by Mr. Lucien Eaton, in your issue of November 19. I have been interested in this subject for some time and would call attention to the fact that scrapers have been used successfully for several years in the coal mines, notably those of the Hudson Coal Co., operating in the Anthracite region, near Scranton, Pennsylvania. The system there used and known as the Evans Scraper Loading System, is well illustrated in Bulletin No. 1, Engineering Development Co. of America, Scranton, Pennsylvania, and was described in detail by H. D. Kyner of the Hudson Coal Co. in his able paper presented at the Wilkes-Barre meeting of the American Institute of Mining and Metallurgical Engineers in September of this year. This system has been used successfully in delivering coal to the haulage-way from 'rooms' up to 400

ft. in length. One hoist and scraper outfit is commonly used to serve four rooms, the hoist being set on the gangway in a position centrally located between the rooms. I have seen this apparatus working in a flat vein averaging only 20 in. thick, all hand-shoveling being eliminated. In the operations to which I refer, the difficulty in dragging the scraper around right-angled turns, which was mentioned by Mr. Eaton, has been successfully overcome by the use of an open-frame snatch-block from which the rope is thrown after the scraper has reached the point of turn, and a vertical drum or buffer which guides the scraper around the turn. For a more complete description I would refer those interested to the bulletin and paper above mentioned, and would recommend the investigation of this system to metal-mining engineers interested in the use of scrapers for underground work.

In my earlier experience in the Western metal mines and later experience in the coal mines, I have often remarked the lack of interchange of ideas between engineers engaged in metal mining and those engaged in coal mining. I believe that such interchange of ideas might often prove of mutual benefit, though I realize that in many particulars the problems involved are very different.

Cleveland, November 21.

Errors Latent in Mine Sampling

The Editor:

Sir—I have read Mr. Morton Webber's article, in your issue of November 5, with a great deal of interest, particularly the latter part relating to the Aurora Consolidated, with which property I am familiar in a general way. My reason for dropping you these few lines is to call attention to the similarity between the conditions at the Aurora Consolidated property and the Bodie mines, of which I was manager a number of years ago. At Bodie we had the small cross-veins in a great many of the orebodies. You will recollect that attention was first called to them by R. Gilman Brown some time in the latter 'nineties. My experience at Bodie stood me in good stead when I again encountered the same condition in Nicaragua. Possibly you recollect my article, published in November 1912, relative to the mines of the Chontales district of Nicaragua. At that time I called attention to the cross-veins which Mr. Webber terms "willow" veins. In operating properties in Nicaragua I noted cross-cuts driven at irregular intervals. They are not all at right angles to the vein, however; in fact, previous profitable operations by the old-timers in that district were based entirely on following these cross-veins and what success I attained in the district during my four years stay was entirely due to following these cross-veins, which contained ore far richer than that in the general average of the main vein. A complete sampling of the Esmeralda mine by the Arroya-Babalonía interests showed an average of about \$5, whereas my records during the time that I operated the property showed an average close to \$10 per ton. The difference

is entirely due to the fact that all the ore that was extracted during my operation of this property was taken out along the one wall and along cross or willow veins.

As a result of my experience with properties of this type, in which the distribution of the gold is so irregular, I would suggest that on a deposit of this class shell-sampling, that is, a complete shelling of the roof by means of pop shots, is the only practical manner of getting at the average value of the ore, particularly as most of the metal in these willow veins is usually in the form of coarse gold, which in any method of groove sampling, particularly where the values are at right angles to the vein, and naturally tend to follow grooves, are apt to give one an error in sampling, with serious consequence, although I hardly see where a dirty roof should mislead any engineer who has had experience in previous sampling of mines of any magnitude. In fact, one of the first requisites of sampling, in my estimation, particularly on a gold property, is a thorough cleansing of the roof either by means of a wire-brush or brooms, using water with which to remove the finer accumulation that always is found in old mines.

New York, November 9.

ARTHUR FEUST.

Technical Writing

The Editor:

Sir—The correspondent in your issue of November 5 who criticizes the letter of Mr. Paul R. Cook (in your issue of October 29) must have been in a bad temper. Perhaps that is the reason he signed as an anonymous 'Engineer-Journalist'. He begins by saying that Mr. Cook tires the reader by his verbosity, and then he writes a letter 50% longer on the same subject. Mr. Cook had made what seemed to me an excellent argument in a single column; the anonymous one splits hairs over it for a column and a half.

The principal point at issue seems to be: What type of article best suits the average reader of the mining-engineering weeklies? Mr. Cook suggests that condensed one-page articles are best, because the expanded (and sometimes padded) eight-page effusions are generally too long to read. The authors of these long articles are likely to be more intent on the prestige that a long article gives them than on condensing their observations for the benefit of the reader. This does not apply to the occasional long article of so interesting a writer as yourself, but to the average contribution. The protest of Mr. Cook seems to me well taken. Long articles seldom are read; short articles are. Then comes in your anonymous 'Engineer-Journalist' and drags his red herring across the trail. The practical man, he says, writes longer articles than the skilled journalists that produce the eight-page articles. The practical man is rather an ignoramus anyway, and never has learned to write; he can not criticize the article of a skilled journalist, nor can he think clearly and express himself succinctly. Obviously the anonymous one has a poor opinion of the practical man, and a high opinion of the skilled journalist. Of course, if the

eight pages of the long article are full of meaty interesting material, it is not too long. Usually, however, it is meaty and interesting only in spots, like the curate's egg at the bishop's table. Possibly a long article interesting only in spots would attract more readers if changed into three or four short articles, each written around an interesting idea. The long transitions could then be omitted, and much routine or obvious material condensed considerably. More thinking by the writer of the article would be necessary, and the pages of the periodical would not be filled so readily, but the readers would gain, I believe.

P. B. McDONALD.

New York University, November 11.

Sundry Observations

The Editor:

Sir—Mining engineers would hardly expect to find one of the best private collections of specimens in a candy store, but such is the case in New York. The hobby of M. L. Morgenthau, president of the Mirror Candy Co., a well-known concern, is the collecting of specimens, and in the rear of the firm's store on Broadway, near 43rd street, is a splendidly arranged display of hundreds of metals and minerals, in the rough and polished, worth many thousands of dollars.

Chains should receive attention just as hemp or wire ropes do, that is, they should be put away carefully when not in use. A friend connected with accident insurance recently informed me that in lifting a girder, a chain sling broke, killing a man, and the contractor using the chain had to pay compensation. It was proved that the chain had become crystallized, therefore the contractor was using faulty equipment. It is argued that the more a chain is worked the better its physical condition, but if used today and then thrown down anywhere, exposed to the weather, for weeks perhaps, the metal is likely to change in structure and become weaker. Large chains may be tested for ductility or brittleness by a magnetic system, similar to that for testing steel rails.

The tests conducted by the U. S. Bureau of Mines, in connection with ventilating the Hudson River Tunnel, are finished. I witnessed the last run, and found it extremely interesting. A motion picture was taken of a test and all apparatus, and will be added to the Bureau's library of films for distribution throughout the country.

During a visit to an open-hearth furnace plant and steel-rolling mill I noted the 'upward' pouring of 3-ton ingots, and wondered if at any stage in the melting of copper, lead, and zinc, or other metals at smelters or refineries this method would be of any use. Of course, the idea in pouring steel this way is to prevent shrinkage and 'piping' in the ingot. A number of molds stand over holes in the top of a hollow base-plate into which the steel is poured from the bottom of the ladle, and the metal rises quietly from the bottom of the mold until full.

M. W. VON BERNEWITZ.

Pittsburgh, Pennsylvania, November 17.

The Design of Flotation Plants

By Arthur B. Parsons

INTRODUCTION. It is safe to say that nothing else can convey, in convenient and intelligible form, as much general information regarding a concentrating plant as a flow-sheet; with this idea in mind I have prepared the eight flow-sheets reproduced in this article. Each represents the scheme of treatment that is being, or will be, used in a plant designed recently. The Nevada Consolidated flow-sheet is that of Section 4, which was completed just prior to the shutting-down of the plant at McGill, early in April. The other sections will be remodeled to conform in essential features to No. 4. The Copper Queen, Utah Consolidated, and Simon Silver-Lead mills have been completed within the last few months and are ready to operate. The starting of the first two will necessarily await the revival of the copper market, while the Simon company is waiting for the completion of the transmission line that will bring electric power from Hawthorne to its property. The Cerro Gordo plant has been in operation for a few months; the Boston & Montana plant is almost ready to run; and construction work by the California Rand company should be completed in December.

The reader will note that the plants in the accompanying tabulation are situated in six different States; that there is no connection whatever between the various companies; and that no two of the plants were designed by the same man or by the same organization. Moreover, the capacities vary over a wide range, and all of the metals that are commonly recovered by flotation concentration are represented in the list. No attempt has been made to show in the table all of the interesting facts, but rather to indicate some of the significant features in the choice of methods and machines. The comment that I make is based, not alone upon facts revealed in an analysis of these few plants, but also upon information gained from discussions with sundry well-known metallurgists. Naturally, no detailed discussion of the merits of different methods or machines can be undertaken in a single short article. My object, primarily, is to indicate tendencies in the design of plants and in the selection of equipment.

GENERAL FEATURES. Among the outstanding developments of a general character in mill-design are (1) simplification of the scheme of treatment and an accompanying compactness of the plant; (2) the use of reinforced concrete in places where wood and steel generally have been used; (3) the more efficient use of electric power, especially by means of individual motors for single machines, and improved devices for controlling motors; and (4) the tendency to choose the machine or equipment that is as nearly fool-proof as possible and that can be relied upon to perform efficiently with the minimum of

lost time; continuity of operation is recognized as vital to the attainment of low cost.

One obvious reason for the small area occupied by a modern plant, as compared with the old type of concentrator, is the utilization of froth-flotation, but improvements in the details of modern design have been an important factor. For example, the fine-crushing department of the Utah Consolidated mill, which was designed and built by the General Engineering Co., of Salt Lake City, covers an area of only 161 by 62 ft., the overall length of the entire plant is only 260 ft., and a large portion of it is only 30 ft. wide. This is small for a concentrator having a daily capacity of 1000 tons. All the machinery in the fine-crushing department, with the single exception of the classifiers, is driven by individual motors, through either chain-drives or Lenix drives. The classifier-drives are so arranged that traveling cranes have clear passage in every direction. This calls attention to an important factor in permitting economy of space, and, incidentally, the efficiency and continuity of operation, namely, the increased use of overhead cranes, by means of which large machines can be removed bodily and replaced by others when repairs are necessary. The wide application of cylindrical mills has stimulated progress in this direction. In a plant of large capacity a spare ball-mill can be substituted in a few minutes for one that needs re-lining.

Apropos of the extensive use of reinforced concrete, numerous illustrations may be cited. The Magna plant of the Utah Copper Co. was shut-down in December 1919, and during 1920 the crushing and roughing-concentrating sections were re-built. Those who are familiar with the old plant would scarcely recognize the secondary-crushing department today. The gallery-floors, elevator-housings, rake-classifier boxes, stairways, feed- and discharge-boxes for the concentrating tables, feed-pipes for the Marcy mills, sundry launders, and miscellaneous tanks are now made of reinforced concrete.

In the Copper Queen mill, at Bisbee, concrete construction has been adopted extensively. Among the places where the use of it is novel may be mentioned the flotation-cells, which are built of reinforced concrete slabs 2½ in. thick, caulked into 3-in. grooves in the concrete floor that will form the bottom of the cell. Dorr thickener-tanks, Blaisdell tanks, and various storage-tanks likewise are constructed of reinforced concrete. Concrete is used generously in the construction of the new units in the Nevada Consolidated mill. Naturally, the companies whose ore-reserves are large, and with whom low cost of operations is more vital than low initial cost, will be justified in going further in concrete construction than will the companies whose mines have a

TABULATION OF FEATURES OF

Name of company	Nevada Consolidated Copper Co.	Copper Queen Branch, Phelps Dodge	Utah Consolidated Mining Co.	Smuggler Union Mining Co.
Name of designer	George C. Riser and D. D. Moffat	H. Kenyon Burch	General Engineering Co.	Walter L. Reid
Capacity of plant, tons per day	12,000	4000	1000	1000
Location of plant	McGill, Nevada	Bisbee, Arizona	Tooele, Utah	Telluride, Colorado
Principal metals recovered	Copper	Copper	Copper	Lead, silver, gold, copper, zinc
Breaker	McCully gyratories (2 stages)	Blake, and Gates gyratory	Telsmith gyratory
Primary crusher	Rolls	Disc-crusher	Traylor rolls
Secondary crusher	Rolls	Marcy rod-mill	Allis-Chalmers ball-mill
Grinding mill	Marcy ball-mill	Marcy rod-mill	Tube-mill
Concentrating tables used	Garfield and Wilfley	Plato	None	Wilfley
Method and purpose of table concentration	To remove a finished concentrate before flotation	Used before and after flotation to make two finished concentrates	The ores are concentrated on tables in a separate plant; the tailings are treated by flotation
Type of flotation used	Air-cells	Air-cells	Air-cells	Air-cells and agitating machines
Secondary flotation treatment	Air-cells as cleaners	Air-cells as cleaners	Air-cells as cleaners	With one kind of ore, tailing from machine is cleaned in air-cells
Type of flotation reagents	Soluble fractions of coal-tar, and lime	Oils	'Alphabetical' reagents and lime	Oils
Method for dewatering of concentrate	Table product in Dorr classifier. Flotation product thickened and filtered in Oliver machine	Coarse-table product in Blaisdell tanks. Fine is filtered in Portland machines

less certain length of life. The very substantial character of the construction is partly the result of, and is justified by, the simplification of the process of concentration. Five years ago a mill-designer scarcely would have been warranted in using reinforced concrete, because of the probability of having to tear it out to provide for alterations in the flow-sheet or for the substitution of new machines.

In connection with concrete I may mention the use of 'gunite' at the Smuggler flotation plant at Telluride, Colorado. The building is of structural steel, the roof of which is made of No. 22 galvanized corrugated iron, protected on the inside with a double layer of $\frac{1}{4}$ -in. asbestos sheeting and two layers of tar-paper on poultry-netting. The under surface is 'gunited' for protection from cold and from fire. The walls are also coated on the inside with 'gunite', reinforced with $\frac{3}{8}$ -in. 'Hy-Rib' metal lath. It should be remembered that the winters in the San Juan region of Colorado are severe.

For a long time electricity has been recognized as the most desirable form of power for operating concentrators. It is not the more general use of electricity, but rather the recent improvement and refinement of its application, that is notable. The use of individual motors for separate machines has increased tremendously. The extreme is probably reached in the Copper Queen mill, in which individual one-horsepower motors are provided for the concentrating tables; but the tendency is evident everywhere. Among the advantages are the following: Simplification of transmission and economy of space by the avoidance of awkward line-shafts, counter-shafts,

and flapping belts. Direct gear-connections or short chain-drives are almost invariably used in the newer plants. This method of applying power diminishes materially the cost of mechanical maintenance by avoiding the incessant re-lacing of belts and occasional re-aligning of shafts. It also makes the work of the operator less hazardous. Perhaps the greatest advantage, however, is the economy resulting from the elasticity of operation. Any particular machine that is not required, or that is in need of repair, can be shut-down quickly and conveniently without interfering with other machinery, provided, of course, that it is possible to divert the feed elsewhere, temporarily. Although it may be that the combined electrical efficiency of a large number of small motors is less than that of fewer large ones, this is more than offset by the fact that when a machine is not operating the total power supplied to the plant is reduced by the entire amount represented by that motor. Figuratively, with this system of supplying energy there is no 'overhead'—represented by auxiliary transmission machinery—to be divided among the individual machines.

Rapid advance has been made in the development of methods for automatic or semi-automatic control. Credit is due to the manufacturers of electrical equipment for improvements both in the design of apparatus and in the development of schemes for using it. Instead of the ticklish business of operating the old-time starting-box with the attendant danger of burning-out the motors, and of personal injury, the millman in a modern plant has only to press a button, situated near the machine

EIGHT NEW FLOTATION PLANTS

Name of company	Boston & Montana Milling & Power Co	Simon Silver Lead Co	California Road Silver, Inc	Cerro Gordo Mines Co
Name of designer	H. S. Gieser	W. Duan and C. D. Kaeding	M. N. Colman	Henry Hanson
Capacity of plant, tons per day	500	150	100	75
Location of plant	Wise River, Montana	Mina, Nevada	Randsburg, California	Keeler, California
Principal metals recovered	Silver	Lead, silver, zinc	Silver, gold	Lead, silver
Breaker	Telsmith gyratory	Gates gyratory	Blake	Blake
Primary crusher	Provision for rolls to increase capacity	Kennedy gyratory	Hendy ball-mill
Secondary crusher	Hardinge mill	Marcy ball-mill
Grinding mill	Hardinge mill	Allis-Chalmers tube-mill	Hendy ball-mill	Marcy ball mill
Concentrating tables used	James	Universal Deisters, Wilfley	Deister-Overstrom	Buchart
Method and purpose of table concentration	In series preliminary to flotation	To separate lead and zinc minerals in the flotation concentrate	As pilots or barometers to regulate operations	To clean flotation tailing
Type of flotation used	Agitating machine (Janney)	Agitating-machines	Agitating-machines	Agitating machines
Secondary flotation treatment	Similar machines for cleaning	Lead floated in first machine; zinc in second	None	None
Type of flotation reagents	Oils	Oils	Oils and calcium polysulphide	Oils and sodium sulphide
Method for dewatering of concentrate	Flotation concentrate thickened and filtered in Oliver's	Thickened and filtered in Oliver's	Dorr thickener	Flotation concentrate thickened and filtered in Oliver

that he desires to start, and automatic devices do the rest; they supply the proper amount of power for starting and then decrease the input according to the requirements; automatic compensators provide for subsequent fluctuations. Men with little skill are able to operate the plant, and possible abuse to the electrical-, transmission-, and mill-machinery is prevented. 'Remote control', by which I mean the placing of the controlling button in an unexposed place, makes for safety to the operator. One refinement is the use of devices for 'interlocking' control. Arrangements are made so that a group of machines, the operations of which are interdependent, are controlled automatically by a single button in such a way as to assure starting or stopping of each machine in proper sequence and at the proper time. The motors for an elaborate system of belt-conveyors, for example, may be interlocked so as to preclude the possibility of costly spills such as occur frequently when belts are not started or stopped in proper sequence. The net result is that fewer men and less-skilled men are able to operate the plant at maximum efficiency. Some economy of power is a coincidental advantage.

The fourth general tendency that I mentioned is the selection and arrangement of equipment that offers the best prospect of affording continuous and steady operation. Three units that can be kept in operation at full capacity 95% of the time, year in and year out, are the equivalent of four units of the same nominal capacity that are shut-down and undergoing repairs 29% of the time. This is patent, of course; but I am inclined to believe that designers of mills are recognizing the fact to

an increasing degree. The wide popularity of ball-mills is due in part to the advantages derived from avoiding mechanical difficulties. Feeders that are positive as well as uniform in their operation; improved drives for all machines, as mentioned heretofore; reliable equipment for elevating and conveying material, both wet and dry; reserve or stand-by pumps and similar units; all these and other features have as one object the continuous and regular operation of the plant.

The provision of bins and tanks, as reservoirs, at various points assists in obtaining the maximum work from the plant. For instance, bins that have sufficient capacity to supply the grinding department with finely-crushed ore for a 48-hour run, can be utilized to enable either the crushing or the grinding department—which should be independent of each other—to shut-down for a day or more without affecting the operation of the other. Somewhat similar considerations prompted the General Engineering Co. to place a stock-tank between the Dorr thickeners, in which the concentrate is dewatered, and the Oliver filters. This tank affords storage that will avoid possible embarrassment from an accumulation in the thickener when one of the filters is being re-covered.

ROCK-BREAKERS. An interesting point is the selection of a 66 by 84-in. Blake-type jaw-crusher for the initial breaking of steam-shovel ore at Bisbee, in preference to a machine of the gyratory type. This breaker will be set with an 8-in. opening and will be followed by No. 9 Gates gyratories. The Telsmith gyratory has numerous adherents; it has been installed in two of the eight plants

In each of the flow-sheets shown here a Dorr classifier is used in closed circuit with the mill. This seems to be standard practice and is founded upon well-established tests, except, of course, with respect to the selection of

TABLE CONCENTRATION. Generally speaking, tables for gravity concentration have a place in most plants of recent design: there is, however, a wide range in the par-

GRINDING AND CLASSIFYING. A ball-, pebble-, or rod-mill of some kind is used, almost without exception, for grinding. So far as I can determine, each type has its adherents, who, for reasons that seem sufficient to them, prefer one or the other. There is no question, however, but that the use of rod-mills is gradually gaining headway. The inefficiency of the long tube-mill has apparently been proved, even when sliming is desired. The General Engineering Co. has selected 5-ft. mills, 12 ft. long, for grinding so that 90% passes 200-mesh. The

ment is apparent. The new standard Callow rougher, 36 ft. long, consists of twelve 3 by 3-ft. units; it is more conveniently operated and repaired, and is a much more efficient unit than the older type of Callow. The Janney equipment recently introduced is known as the Standard straight-agitation machine, requiring no auxiliary air; the machine itself is preceded by a special emulsifier. The new Minerals Separation machine has no separate spitzkasten compartment for frothing; a horizontal baffle in the agitating-compartment serves to restrict the violent commotion to the lower part, thereby permitting the froth to form and overflow without trouble. The Allen cell, used at the Smuggler Union plant, is a simple and convenient cell of large capacity. The largest single cell is a wooden box, 40 ft. long and 36 in. deep; the bottom is 30 in. wide and has no slope whatever. The sides are inclined inwardly so that, at the top, the cell is about 18 in. wide. This feature is credited with affording a decided advantage in obtaining a clean concentrate. A number of agitating-machines in which the stirring device revolves on a horizontal shaft have been developed and are in successful operation. What seems to be needed is a slow-speed machine that can be built, operated, and maintained more economically than can most of those depending upon high-speed impellers for mixing. Experimental work in this direction should prove technically profitable; but it is doubtless less attractive than it would be but for the status of patent litigation.

An interesting feature is the development of soluble flotation reagents that require no agitation; they diffuse in the water of the pulp without any stirring whatever. At one plant several thousand tons of ore containing 2 to 2½% copper in the form of chalcopyrite, and an exceptionally high proportion of pyrite, has been treated. The ore was crushed so that 85% passed 200-mesh and was floated in pneumatic cells with a mixture of alphanaphthylamine and xylidine (soluble coal-tar derivatives known as XY reagents). A distinct selective separation of the chalcopyrite as against the pyrite was effected; a concentrate assaying from 11 to 13% copper and containing 90% of the total copper of the ore was obtained.

A detailed discussion of the reagents used is beyond the scope of this article. Obviously, selective work will be required to float first the lead and subsequently the zinc, at the Simon plant; most of the lead in the Cerro Gordo ore is in the form of carbonate, and the silver is a chloride; the use of sodium sulphide has proved effectual in sulphidizing the lead and silver minerals, so that they become amenable to flotation.

SECONDARY FLOTATION TREATMENT. In the larger plants the flotation treatment consists of a roughing concentration followed by cleaning of the rougher-froth in a second distinct unit of smaller size than the first. This practice has been discontinued at the Smuggler Union plant; instead, a finished concentrate is taken from the first few compartments of either the air-cells or the M. S. machines, while the froth from the remainder is returned to the head, where it joins the

original feed. This is the procedure at the Simon, Cerro Gordo, and California Rand plants. The plan, of course, is especially applicable where but one flotation unit is used, but the obvious simplification of operation seems to warrant its serious consideration elsewhere. A variation in the operation of the M. S. machines is noted in the California Rand mill, in which no froth is removed from the first three compartments; they act as agitators only. A still more complicated arrangement appears in the flow-sheet of the Simon mill; in it the shading of a compartment indicates that no froth is taken from that particular one. The original feeds are introduced in the third and fourth compartments, respectively, of the 'lead' and 'zinc' machines, the returned middlings occupying the head-cells, where they are cleaned. This seems to be a sensible arrangement.

A novel alternative flow is indicated in the Cerro Gordo flow-sheet. Normally the overflow product from the classifier goes to the M. S. machine, the tailing from which enters an Allen cone, functioning as a classifier. The overflow is discarded and the spigot-product is sent to the Buchart table. The variant would be to divert the classifier product to the Allen cone; the overflow would form the flotation feed, and the spigot-product, as before, would form the feed for the table. This scheme would increase the capacity of the plant, but would probably give a lower recovery. The expectation is that the practice first described will be retained.

DEWATERING OF CONCENTRATE. Here Dorr equipment seems to monopolize the field; froth-concentrate always finds its way immediately into Dorr thickeners; and almost invariably the thickened product is dewatered further by Oliver filters or, in some places, by Portland filters. Machines ranging in size from 4 by 6 ft. up to 14 by 16 ft. are used, generally with satisfaction. It is apparent that the high freight-rates make the shipment of much moisture in concentrate especially undesirable; a practicable method for dewatering froth to 4 or 5% moisture at low cost would be very acceptable; but no process seems likely to displace the vacuum drum-filter. One solution of the marketing problem is the reduction of the concentrate to bullion at the mill; this is engaging the attention of metallurgists, but it has no place in this article.

The Smuggler Union company has paid unusual attention to the design of equipment for handling the froth-concentrate. The finished product of the flotation-cells goes to Dorr bowl-classifiers for separation into a coarse product, which falls directly onto 16-in. belt-conveyors; and a slime that is thickened in Dorr thickeners. The thickened pulp is elevated to a Portland filter, placed immediately above the thickeners, and arranged with large and positive quick-discharge valves by means of which the hoppers can be emptied into the thickeners below in case of trouble from the shutting-off of power or from other causes. The elevation of the filters also permits the use of a dry-vacuum system with a barometric water-column. The removal of the coarse sand in the bowl-classifier and the provision for emptying

tial. This may be accomplished by using an apron- or pan-feeder, or some kind of a revolving-drum feeder. There are many designs of both types. Two particularly good drum-feeders installed at the Simon Silver-Lead mill are patterned after some originally built at the Dome mill in Ontario. The remodeled Challenge feeder is satisfactory in some places. The improvement in feeders has accompanied the general tendency to decrease the

DEVICES FOR HANDLING MILL-PRODUCTS. Devices for more efficient feeding, conveying, elevating, and pumping have been developed. Positive and uniform feeding, subject to easy regulation, is being recognized as essen-

Copper Queen	Air-lift
		Belt-and-bucket elevator
Utah Consolidated	...	Belt-and-bucket elevator
		Wiltley sand-pump
Smuggler Union	Air-lift
		Dorr diaphragm dump
		Belt-and-bucket elevator
Boston & Montana	...	Belt-and-bucket elevator
Simon Silver-Lead	..	Krogh pump
California Rand	Belt-and-bucket elevator
		Krogh pump
Cerro Gordo	Belt-and-bucket elevator

The most significant fact here is that six of seven plants are equipped with belt-and-bucket elevators for lifting pulp. I believe that one of the important reasons for this apparent preference is a point to which I have already alluded: the importance of continuity of operation. An elevator is expensive to erect, but if it is designed properly it will run without delays and with little attention; it requires no packing and no replacements until the belt is worn out; it consumes little power. Incidentally, I may draw attention to the contrast between 'wet' elevators and 'dry' elevators. The latter are being displaced in many instances by belt-conveyors, with consequent economy of no little importance. The belt-conveyor, with idlers fitted with ball- or roller-bearings, is a deservedly popular contrivance; whether horizontal or inclined, it gives cheap, clean, and steady service.

MISCELLANEOUS ITEMS. A few small items are worthy of mention. One is the use of the vibrating screen for economical and efficient sizing. When its virtues are more widely known it should be used more extensively. Another is intelligent lighting of mill-buildings. Both the Utah Consolidated and Smuggler Union plants will be illuminated with a comparatively small number of high-candle-power lamps equipped with suitable reflectors and suitably placed to afford proper diffusion. Small drop-lamps, like those generally found in mills in the vicinity of each piece of machinery, have been discarded entirely. Mention has already been made of the practice of providing 'spare' or 'stand-by' pumps, blowers, compressors, and other small but vital units of the equipment. This is not new; the significant point is that the idea is being given wider recognition by those who are designing modern mills.

A STANDARD MILL. The treatment of every ore is a problem in itself and the design of a plant must be governed by the particular characteristics of the ore. Nevertheless it may be interesting to outline roughly the flow-sheet of a mythical 'standard' plant, choosing the equipment according to the preponderance of opinion held by a large number of metallurgists as to the merits of various machines. It will be advisable to imagine two plants. 'A' will have a capacity of 2000 tons, 'B' of 100 tons.

A	B
Gyratory crusher	Blake crusher
Disc-crusher

Air-flotation cells	Agitating flotation machine
Concentrating-tables	
Dorr thickener	Dorr thickener
Drum vacuum-filter	Drum vacuum-filter

Doubtless no one will agree entirely with the interpretation of the tendencies of modern practice indicated by the selections made above. As a matter of fact, the task was more difficult than I imagined it would be. I offer it simply as being the result of my discussion with men who are actually engaged in designing, building, and operating flotation plants.

Bentonite

The name bentonite, according to a U. S. Bureau of Mines bulletin, has been applied to a group or series of clay-like materials characterized by an alkaline oxide and alkaline earth content of 5 to 10%, fine-grain size, high absorptive powers, and, usually, strong colloidal properties. Bentonite probably represents no mineral of fixed composition, and its physical properties vary considerably. The type material from Wyoming is light yellow or greenish-yellow in color, but from other localities it may be cream colored, white, gray, pink, dark brown, or even black. It is exceedingly fine grained, very plastic, and highly absorbent. The appearance may be dull or powdery, but a freshly-cut surface usually has a waxy lustre. Some varieties have the appearance of wax and may be cut into thin translucent shavings. The fracture of the type material is roughly conchoidal, that of other varieties is platy and shale-like; others have no typical fracture. Bentonite is highly absorbent; when wetted it will absorb more than three times its weight or seven times its volume of water. Some varieties when wetted with water expand to more than six times (some experimenters report eight times) their original volume. The wetted material is exceedingly smooth and soft and feels like soft-soap. Unlike most clays, bentonite is easily fusible at a comparatively low temperature. Under a high-power microscope bentonite seems to consist of extremely small, more or less rounded, grains of uniform size, but the texture of most varieties is so fine that individual grains cannot be distinguished. Some varieties, when finely ground and thoroughly agitated with water, will stay in suspension indefinitely, forming a translucent gelatinous mass. The addition of small amounts of acids or sodium chloride seems to have little or no tendency to aid coagulation or settling. Some of the minerals of the bentonite group have the property of allowing easy replacement of the alkaline and earth oxides, one with another. If hard water containing calcium sulphate be passed through a mass of bentonite containing sodium, the calcium sulphate is changed to sodium sulphate and the sodium in the bentonite is replaced by calcium. The process is reversible; the bentonite may be rejuvenated by passing through it a solution of sodium chloride. The sodium is restored to the bentonite and the calcium is removed as a chloride. It is probable that carbonates are removable in the same way. This easy replaceability of the alkaline oxides may have an important bearing upon the physical properties of the bentonites. For example, it is possible that the differences in colloidal properties of various bentonites may be due to variation in relative percentages of the alkaline oxides.

Electricity in the Development of the Mining Industry

By Girard B. Rosenblatt and Graham Bright

*The subject that interests all industry most fundamentally is money. The mining industry is no exception. The future of electrical power in the development of mining depends upon what it can accomplish expressed in terms of money. It is our intent to outline briefly some ideas regarding the influence of electrification upon the lessening of mining costs. We will endeavor to point out the lines along which such development may logically be expected, and the things that may be anticipated during the next decade in the way of electric-power supply for mining and metallurgical operations.

Further use of electricity in the mining industry will most logically be along three lines, namely:

(a) The displacement of manual labor.

(b) The supplanting of present steam by electric power.

(c) The development of new metallurgical processes.

(a) Electric power will replace manual labor more and more as the supply of cheap labor continues to decrease, and as the laboring man develops an objection to monotonous occupation, which objection is always incident to an improvement in the standard of living. Mining and metallurgical operations consist largely of moving and treating material in bulk. Man-power, except in special and specific instances, is not a cheap way to move bulk material. Electric power is the most logical substitute because of the flexibility of its application, the economies that may be effected by its use, and its reliability when properly installed. Already the electric locomotive, in the smaller sizes, has displaced largely hand-tramming; mechanical shoveling machines are replacing the 'mucker' underground; while scoop-loaders, bucket-elevators, and belt-conveyors continue to replace shovels operated by men with strong backs and weak heads. Further developments in the replacement of manual effort by electric power will depend upon a realization of what can be saved by displacing human labor, and upon the development of equipment and machinery that will be more flexible than present apparatus, that can be operated more accurately to simulate the action of an efficient man, and that can be economically purchased in units small enough to displace a small group of men in handling small tonnages. The advantages of mechanical handling today are generally appreciated when large tonnages are considered. Further progress will come through the perfection of equipment to displace manual labor in the handling of smaller tonnages, and the education of the public toward appreciating the advantages of such equipment.

(b) Electric power will supplant steam power as hy-

dro-electric energy distributed by public-service corporations becomes more generally available, and as methods of generation become more efficient. Already we see the net-works of the big central-station organizations of the country spreading out over the mountains to localities where basic raw materials are being produced. Where such central-station power is available the increase in the use of electricity will be rapid. Where central-station power is not available, as in some of our desert regions, wider use will depend upon the obvious economies of generating electricity in bulk and applying it in parcels to the performance of mechanical operations. Electricity as a power for hoisting, pumping, ventilating, compressing air, transportation, and milling, is inherently more economical than steam under most conditions, because of the high efficiency of electrical equipment, the convenience of its use, its low maintenance charges, and its operating simplicity. The increased use of electricity in performing those operations now very commonly performed directly by steam depends upon the education of the using public properly to view their power problems as an entity, and not to base decision upon a comparison alone of tabulated efficiencies of individual equipment.

(c) One of the greatest opportunities for the lowering of metallurgical costs lies in the commercial development of processes using electric power directly for the production of thermal effects, and for electrolytic action. Electric furnaces have come to stay in the production of ferro-alloys. It is to be expected that eventually electric smelting of certain of the base metals may be feasible and economical. Such smelting would permit the operation of many isolated properties at a decided advantage. In the meantime great strides are being made in direct precipitation of pure metal from liquors produced by the leaching of mine ores, such as the production of copper at the plant of the New Cornelia Copper Co. at Ajo, and of zinc at the plant of the Anaconda Copper Mining Co., at Great Falls.

Experiments that have been conducted in the direct production of what in the past have been considered fabricated articles, like copper 'shapes', have been most encouraging; we believe that in the not far distant future we may expect to see material, which has always been considered as of secondary manufacture, produced directly by electrolytic action in the leach-liquors resulting from the direct treatment of ore.

In the final analysis, the further utilization of electric power in the mining and metallurgical industries will depend upon the answer to the question: Does it pay? To obtain a true answer to this question it is necessary that we consider the entire problem presented in connection with any given application. It is not sufficient, nor proper, to examine and compare the first costs and effi-

*A paper prepared for the convention of the American Mining Congress at Chicago in October 1921.

encies of electric power with those of some other method of performing a desired operation. The proper way to study the problem is to consider all of the factors that may affect results, and then to determine comparative unit costs. In mining and metallurgy this almost invariably resolves itself into costs expressed in 'cents per ton'.

A fair examination of the individual problem at each mine will frequently show that the application of electricity will effect a saving. Reduced cost per ton means a greater profit on ore mined, and the extension of ore-reserves, because lower-grade ore can be worked within the limit of permissible cost. This is the basic reason that further utilization of electric power is assured in the mining industries.

In discussing the relative cost of electric and of other forms of power, it is not proper to consider the unit cost of power purchased or generated. Rather should we look to the unit cost of power involved in the results accomplished. For instance, in considering the cost of hoisting with steam, generated locally, as against the cost of hoisting with purchased electric power, it is not proper to compare the pounds of steam used by the steam-engine with the kilowatt-hours of electric power purchased for the electric hoist. Other factors enter into the problem. There are the standby losses for the steam-plant when the hoist is not in operation. There are the maintenance costs of the entire steam-plant from coal-pile to crank-pin, to be balanced against the maintenance of the electric equipment. Further, there is the matter of considering whether the flexibility of the electric hoist may not permit a more economical hoisting schedule than would be used with a steam-plant that cannot be left idle without incurring a loss. What the mine operator really wants to know is whether the steam-hoist or the electric-hoist will mean a greater charge per ton for ore brought to the surface; and no factor that enters into this cost should be overlooked in making a fair comparison. The unit cost of energy is only one of the factors that enter into the total which must be considered.

There are three lines along which intelligent study may aid the mine operator to reduce his cost per ton mined by the proper utilization of electric power.

The first is the wise selection of apparatus to do the work that must be done. The second is the efficient scheduling of operations in order to use the power purchased or generated to the best advantage. The third is the possible reduction of the unit cost of power.

The wise selection of electrical apparatus reduces power per unit of work accomplished, eliminates interruptions in operations, and decreases the item of labor required for attention to the process, and for the maintenance of the equipment.

Experience is one of the best guides in the selection of the best equipment to do particular work; but past experience of others should not be followed too blindly. The art of making electrical apparatus is advancing—and advancing rapidly. Holding to past practice, however successful it may have been under conditions that are also past, is frequently a stumbling-block in the road

of progress. The best guide to the proper selection of electrical apparatus is intelligent engineering based on a proper understanding of the fundamental characteristics of electrical apparatus, backed by extensive experience in its application. Today the larger electrical manufacturers are prepared to furnish such engineering guidance to the mine operator.

The use of synchronous motors, in and about mines and milling plants, offers a fruitful field for the reduction of costs by the proper selection of apparatus. A few years ago the synchronous motor was considered to be an unreliable and complicated piece of apparatus. Until comparatively recently this reputation was probably justified. Today the design of synchronous machinery is so well understood that synchronous motors can be applied advantageously to many drives that have in the past been cared for entirely by induction motors. The synchronous motor of today can be manufactured with characteristics to meet the requirements of a large variety of loads, all the way from driving pumps and air-compressors to driving crushers and mills. In its modern form it is a machine easy to operate and control, and it has decided advantages for many applications. For very high speeds and for low speeds it is frequently cheaper to buy, and in almost all cases it has higher efficiency than induction motors for the same work. Its use permits the improvement in power-factor in return for which many power companies are willing to make concessions in their contracts. Its capabilities for correcting power-factor are of further interest to mining companies for the reason that synchronous motors reduce losses in their distribution system, increase the effective capacity of their transformer stations, and improves the regulation of their power-plant supply. The importance of the synchronous motor to the widespread distribution of electric power over long distances, with a resultant economy that must eventually be reflected in lower power-rates, has been capably placed before the engineering profession, by F. G. Baum, in his paper delivered before the American Institute of Electrical Engineers, at the convention held in Salt Lake City, in June 1921.

The developments of automatic and semi-automatic control of electrical equipment has made great progress in the past few years, and it may be expected that in the further use of electric power, mining companies will take full advantage of such control systems. Automatic and semi-automatic control allow large savings in cost by reducing the number of operators required, by permitting equipment to be operated by less skilled labor, and by reducing the consumption of power. Automatically controlled substations are now in use on the haulage systems of some of the larger coal mines. Semi-automatic battery-charging systems are used quite extensively in connection with storage-battery locomotives. Semi-automatic hoisting has been in successful use at Inspiration for several years. The Phelps Dodge Corporation has just installed semi-automatic control on the motors throughout the new Copper Queen concentrator at Bisbee.

Proper scheduling of operations reduces costs by ac-

completing the greatest amount of work for a minimum expenditure for power. Such scheduling depends upon the conditions under which power is generated, or upon the terms under which it is purchased. Frequently a great saving can be effected by the elimination of peak-demands that might be occasioned through the concentrated or simultaneous performance of operations. These might be arranged by proper scheduling to succeed one another so that their power-demands would not be coincident. Much good work along these lines has been done by some of the larger mining companies.

An example of practice in the scheduling of operations to reduce peak-demands, is the operation of coarse crushers in one shift per day, choosing that shift when other operations require a minimum of power. Such practice, of course, means adequate storage capacity between the coarse-crushing and the subsequent milling operations. The investment in such storage-capacity frequently shows an excellent return, due to the saving in operating charges accomplished by reducing peak-demand for power. Another instance not infrequently met, is the charging of storage-battery locomotives during the 'off' shift.

Other opportunities for scheduling operations around the mine and mill so as to reduce peak-demands often exist. For example, it is sometimes feasible to arrange for hoisting ore during periods when the power requirements for other operations are at the minimum. Frequently peak-demands may be reduced by slowing the speed of hoisting so that the maximum demand for power is kept low. Reducing the speed of hoisting naturally lengthens the period required to hoist a given tonnage. Often it is economical to do this rather than to try to hoist all the ore in the minimum length of time.

Some of the larger mining companies in this country have extensive enterprises which consume a large portion of the power from the hydro-electric systems supplying the districts in which they are located. The thought is suggested that some of these large organizations could economically install a system of load-dispatching so that the daily power requirements of their various enterprises could be balanced without interfering with production, yet in such a manner that their total requirements could be met with a smaller investment by the public-service corporations to such an extent that more attractive power-rates could be allowed. Of the possibilities for reducing the unit cost of power, more will be said later.

Where hydro-electric or other forms of central-station power are available, electricity is in common use for pumping, compressing air, hoisting, and milling. Even in such localities, however, individual steam-plants, particularly for hoisting, are not altogether unusual. Rare, indeed, is the mining camp that does not exhibit one or more mines that do their hoisting at least with steam power, despite the fact that cheap electric power is available. Frequently these steam-plants are retained largely because of prejudice against electric power, and the fallacious idea that steam-hoists are more reliable. An unprejudiced analysis almost invariably shows that the reliability of electric hoisting is superior to that of any

isolated steam plant, and that the possible saving due to electrification would quickly return the investment required to permit the replacement of steam power with electric power.

The rapid progress in perfecting mechanical shoveling machines, haulage equipment for small tonnages, car-loaders, car-dumpers, and excavating equipment, offers a big field for the further use of electricity in mining. We expect rapid developments along these lines within the next decade. Other developments that will tend toward further electrification, even though little power is involved, include the perfection of portable electric miners' lamps, shot-firing by electric means, and radio communication between headquarters and remote properties.

In addition to the saving in cost per ton that may be made by the proper selection and application of electrical apparatus, and by the proper scheduling of operations to get the most out of every dollar's worth of power used, there is reason to believe that in the future further savings in the use of electricity may result from a lessened cost per unit of power. The hope for such reduction lies not so much in the increased electrical efficiency of generating or transmission equipment as in the more economical generation and delivery of electrical energy through the adoption of what has been termed the 'super-power' idea.

The idea of a super-power system was conceived by W. S. Murray with the particular idea of reducing fuel-consumption and increasing the reliability of electric power, in the north-eastern portion of the United States, at a time when both these matters were of extreme importance to the continued economical welfare of the nation. However, the idea is not applicable to that particular territory alone; in a modified way it can be applied to the Western regions fed in the main by hydro-electric systems, for which fuel-burning plants are used only as auxiliaries.

Essentially the idea of super-power involves an inter-connection of existing power systems in such a way that the power-supply of a large territory, covering possibly a considerable number of States, may be obtained from a general transmission-system, into which all of the various generating plants feed their output. The general transmission system acts as a sort of equalizing reservoir, much as does the receiver in a mine air-compressor system.

The particular advantages to be gained by such wholesale operation include the following:

- (1) The large diversity factor in the loading of such a system will permit operating all generating equipment and all trunk-line transmission-busses at very high load-factor with consequent economy.

- (2) The production of power can be cared for in efficient large units, and the wasteful small plant operating at poor load-factor can be discarded.

- (3) A united system of this character can take full advantage of the maximum run-off in various streams used for production of power because, due to geographic and climatic differences, the period of high water will not be coincidental in all streams feeding the system.

- (4) It would be possible to develop on a profitable

basis certain hydro-electric power-sites which hitherto had been considered uneconomical due to their distance from the load-centre, even though the unit cost of development at such sites was low.

(5) Power-supply from such a system would be practically free from any interruptions, and continuity of service would be virtually perfect.

(6) A single investment in costly transmission-lines would serve, in whole or in part, a number of generating systems with the consequent distribution of overhead costs over tremendous amounts of delivered power, thus reducing the fixed charge to be carried by each unit of power delivered to the consumer.

Our large public-service organizations in the West recognize all of the basic principles involved in the idea, and incorporate them in their individual operations. Mr. Murray's idea is simply an extension of approved practice to a scale that would permit further economies for the benefit of both the users and producers of power, and for the conservation of our national resources.

Under the conditions that obtain in the Western mining regions the super-power problem is largely one of economical long-distance transmission of electric power. The solution of this phase of the problem is one in which the consumer, as well as the producer, must play his part. As pointed out by Mr. Baum in his excellent presentation referred to above, the addition of synchronous-motor load materially reduces the difficulties of long-distance high-voltage transmission, which gives us another angle from which to view the advantages to be derived from the proper selection of electrical apparatus to assist in reducing the cost of mining.

In closing it may perhaps be of interest to present some data as to the interdependence of the electrical industry and the mining industry. You may be interested to know to what extent the mining industry is at present a user of electric power, and to what extent the electrical industry is a user of mine-products.

During the year 1920 the power generated in the Western States, which embrace the region in which are situated a large proportion of the mines of this country, there was generated a total of approximately 8 billion kilowatt-hours of electrical energy. Of this total about 64 billions was generated by public-service corporations and sold. The electric power used by the mining industry amounted to about $1\frac{1}{2}$ billion kilowatt-hours, or roughly 20% of all the power sold by the public-service corporations.

During the same year 1920 one of the two largest electrical manufacturers in this country built about $2\frac{3}{4}$ million kilowatts of electric-power equipment, and to construct this equipment it used practically 40,000,000 lb. of copper, 850,000 lb. of zinc, 750,000 lb. of lead, 300,000 lb. of asbestos, and 650,000 lb. of mica.

These figures will give some idea of the importance of these industries each to the other; this importance will be magnified still more as a result of the growth of the mining industry that will be permitted by further development, and further use of electric power in mining and metallurgical operations.

Hot High-Nitrogen Gas in a Metal Mine

While investigating the presence of heavy strata gases in certain mines of the East Tintic mining district of Utah, a small local body of light, very hot gas of high-nitrogen composition was noted in one of the mines, states G. E. McElroy, in a U. S. Bureau of Mines bulletin. Observations and analyses indicate that this light gas was resulting from very rapid oxidation of finely disseminated pyrite, in lead-silver sulphide ore. The gas was actually mine-air which had lost a large proportion of its oxygen by reaction with the pyrite. This body of gas was hanging in a local high-spot about 5 by 5 by 5 ft. in size, caused by caving, at the end of a cross-cut. Fifty feet from this spot, an air-current of 6000 cu. ft. per minute was entering the 5 by 7-ft. cross-cut from a raise. On account of the vapor contained in the gas, the bottom level of the gas could be plainly seen and was practically a horizontal plane, but of slightly wavy appearance, coinciding with the point where an acetylene light was extinguished. This body of gas was visited on three occasions and samples obtained by means of evacuated bulbs and by water displacement. The temperature of the gas was approximately 175° F. on all three occasions, so that sampling required thick gloves and quick action. Air three feet below the vapor-line had a temperature of only 120° F., and a relative humidity of 27%. The stratification of the air and gas mixtures was so sharply defined that the sampler could hold his head a few inches below the vapor-level for an appreciable period of time without any noticeable effect other than that due to the high temperature. At one foot below vapor-level, it was 135° F., and the relative humidity was 30%. When a candle and an acetylene light were raised into the gas from below, the candle flame was extinguished at a point two inches lower than the acetylene flame, indicating a drop in oxygen content from about 16% to 12% (oxygen content of normal dry air, 20.93%) in two inches. The analyses and air-free calculations made show that the gas is black damp (defined by Haldane, the English physiologist, as an accumulation of carbon dioxide and nitrogen in proportions larger than those found in atmospheric air) composed almost wholly of nitrogen. That the process of oxidation was still in rapid progress was evidenced by the fact that, although the body of gas occupied not more than 150 cu. ft. and the vapor-level was practically constant, a thin stream of hot gas, estimated at 25 cu. ft. per minute, was flowing along the roof of the cross-cut to the air-current 50 ft. away. The tendency of such a mixture of air and gas to hang to the roof is due to its lighter weight as compared with the mine-air. The difference in weight is due primarily to temperature and humidity. The gas had a musty, sulphurous odor and a suffocating effect when breathed. Attempts to prove the presence of sulphuric-acid vapor in the body of gas were not determinate, although a slight amount was undoubtedly present. The presence of this gas in this mine probably represents the first step in the production of certain heavy strata gases high in carbon dioxide that affect mines in this district.

Impressions of a Journey to Europe

By P. B. McDonald

Columbus was more than two months in crossing the Atlantic, as were the Pilgrim Fathers more than a century later. Although the great liners now make the trip in a week, even the largest of them—a colossus longer than the Woolworth building is high—rolls and shakes in a storm despite the best efforts of modern seamanship. However, a consistent speed of a mile every three minutes for several thousand passengers is a remarkable achievement, and the comfort and cleanliness would make the scurvy-ridden sailors of the old wooden sailing vessels gasp with astonishment. The three thousand miles from New York to Europe can be traveled more comfortably than the three thousand miles from New York to San Francisco.

If the traveler to England goes by a British boat, the week of British conversation and British food prepares him for what is coming. They converse differently from Americans, ending sentences with a rising inflection and sniffing a bit at social inferiors, while their cooking shows less imagination than that of an American contractor's camp. There is a restraint in the atmosphere of England, a sort of obstinacy, as seen in the opposition of their workmen toward changes of design and method; an American professor with whom I talked described it as a woodenness of manner, an inbred devotion to the old ruts. Yet no one can deny that the British do many things better than we Americans. They have a respect for leadership that brings men and matters into a right proportion, and some of their leaders are broader types than could exist in America. For example, the London 'Times' printed recently a series of articles on road reform by Lord Montagu of Beaulieu, a product of Eton and Oxford who has traveled over the world observing methods of transportation, owns 10,000 acres of land, and is interested in wild-fowl, music, and literature. Because of his wide experience and interests, his articles were a discussion of highway construction from the point of view of the engineer, the financier, and the land-owner; that is, he had a broader grasp of the subject and could express his ideas more clearly and attractively than one who was merely an engineer. Moreover it is doubtful whether any American newspaper would devote so much space to one man's opinions on a technical subject.

I did not see in England many representatives of the type of engineer-administrator which America produces in large numbers, executives trained in engineering such as Hoover, and his assistants in the Belgian Relief, or Ketchum and his staff, who administered the war-built town of Nitro, in West Virginia; yet I met in London men who combine a knowledge of pure and applied science to a degree that Americans do not. Many of these scientific thinkers could not make a living in a democracy because they neither bluster nor conform to office regulations, but living in an aristocracy they are able to do im-

portant and valuable work because someone recognizes that intellect can not be standardized into quantity-production but must be allowed to develop as it will. The interest taken in the United States by British newspapers is greater than the interest in things British taken by American newspapers, for the British foresee a commercial rivalry that means a great deal to them, and some of them are not especially friendly toward Americans for that reason.

Going across the English Channel is like going to another world. There is much in England that resembles America, but the American in France feels himself in another civilization. To me it appeared as a survival of the Roman Empire, for the Romans civilized western Europe and held dominion over it for centuries. As the distinguished editor of the 'Engineering News-Record' has remarked, Paris is a triumph of artistic city-planning and is a city that is grown and complete rather than in the transition stage of American cities. The culture of the French is seasoned and mature; it is not in the Main Street stage. One could scarcely observe French families sitting on the beautiful boulevards drinking moderately of wine and beer, with no one getting drunk, without comparing the scene with prohibition America where had whisky is sold at high prices behind closed doors. The excellent manners of the French were a marvel to me; it is truly a revelation how important manners can be. On the other hand the red-tape of bureaucracy and government control is much worse than anything at Washington, and the French are as conservative in many ways as are the British; particularly is French labor antagonistic to improved methods and modern efficiency. However, the French roads are worthy of much praise, as is also the Parisian subway system, both of which E. J. Mehren described in his letters in the 'News-Record'.

Paris is not so modern and fashionable as it is medieval and classical. The slender Eiffel Tower rises over the city to proclaim the new era of steel and the conquest of nature, but life in the streets below harks back to the old Mediterranean civilization that discovered how to live before it bothered about machinery. It is in understanding how to live that the French excel, and so attractive are their boulevards, their art, and their food, that it is something of a shock to pass into Germany; for the Germans, though industrious and thorough, do things with a heavy touch.

Germany seemed depressed only in places. Certain industries that require costly imported raw materials were more or less at a standstill, but many other industries were busy and fairly prosperous. Wherever skilled labor is the principal item in manufacture, German products were competing favorably with those of other countries. Labor, of course, is plentiful and willing to work hard and long. The German people have been unsettled and dazed by the War, and their political sense is not so resistant as that of the Anglo-Saxon, but they are as yet too close to the catastrophe that befell them to realize what it all signifies. Most are continuing their hard work and pushfulness from mere force of habit. As several observers have pointed out, automobiles are scarce

and some cities seem dispirited and saddened, but such are the natural consequence of a long war. On the whole, Germany does not appear worse off than one would expect. The inconvenience of passport regulations and police permits is notably bad in Germany, and travelers are expected to report to the police of each city that they visit, though no one explains this to them. However, there is consolation in the benefit of exchange, and the dollar is particularly potent in Germany. Hotel rooms at 30 or 40 cents per night, and meals at 25 to 30 cents astonish anyone accustomed to New York prices. Moreover the Germans do not suffer so much from this depreciation of the mark as some reports indicate, because their printing-presses have been so busy making paper money that it is fairly plentiful among the population.

Holland has a cosmopolitan tone. It possesses a combination of German, British, and French civilization, and its sturdy burghers have invested in many remote parts of the world. Its wealth is much greater than that of Belgium. Belgium is a little France, and much of the description of France applies also to Belgium.

An American returns to the United States with a new appreciation of what his people have done in building up a great nation; his patriotism is increased by a sojourn in the older countries. A European trip is worth while to give this sense of values and to furnish a temporary detachment from the standardized routine in America. To learn to know one's own country, take a trip abroad.

Loading Converter Matte

By Frank Taylor

*At Copper Cliff the finished converter-matte is poured into cast-iron molds, of which there are 14, housed in a matte-shed along one side of the main converter-building. These 14 molds are divided into two sets of seven each, placed at opposite ends of the matte-shed. Each mold is about 36 ft. long by 6 ft. wide and 4 in. deep, and when full holds approximately seven tons of matte. They are of sectional cast-iron and are held together by tie-rods. The joints are made tight by retort cement. Each mold is divided into five parts by means of sections having a rib on the upper side extending across the mold, except for an 18-in. gap in the middle. This rib creates a line of weakness across the matte after it has solidified, and thus facilitates breaking.

Previous to 1917, the ribbed sections were not used. Men working with bars removed the matte from the molds in the form of large irregular slabs, and these were rolled on short pieces of heavy pipe to the floor alongside, where they were broken up with sledge-hammers to a size convenient for handling. The broken matte was then loaded by hand into wheel-barrows, in lots of 400 lb., and wheeled on to an escalator which in turn carried it to a platform at the level of the decking of a standard-gauge railway car, into which it was then wheeled and dumped. This method entailed a consider-

able amount of manual work, and when, in the summer of 1917, labor became scarce, and production was being increased, it was realized that some mechanical method must be devised for loading the matte—or, at least, some method that would accomplish the loading with a minimum of labor. The system described herein was evolved, and has been found satisfactory.

Over each group of the matte-molds there has been erected a trolley-crane, on I-beams which extend the length of each group. The crane consists of one 10-in. I-beam, hung on 4-ton Brown trolleys. From this I-beam is suspended an air-lift, 12 in. diameter with 6-ft. stroke, capable of raising four to five tons with air at 80 or 90 lb. The air-lift is supplied with air by a hose which is hung on a cable running parallel to the crane-track beams. The crane is moved by an electrically-operated double-drum hoist, with $\frac{1}{2}$ -in. cable attached, and passing over a return-sheave at each end of the matte-shed. The hoist is situated between the two sets of molds already mentioned, and is on a level with the crane beams, both of which are operated from this point.

Before the matte is poured into the molds, a cast-iron lifting-block, with an aperture for a hook, is placed in the centre of the area marked out by a pair of ribs, and at the same time the molds are given a lime-wash to prevent the matte adhering to the iron. Soon after the matte has solidified, and while it is still hot, the crane comes along and the air-lift is hooked to the lifting-block. In this way a slab of matte, about 6 ft. square and 4 in. thick, and weighing about $1\frac{1}{2}$ tons, is picked up and transferred to a loading-station, of which there are two, one at each end of the matte-shed.

The loading-station consists of a set of grizzlies at the floor-level, made up of standard 80-lb. rails in cast-iron chairs. Below the grizzlies is a small concentrate pocket, in which stands a side-dump, steel car that has a capacity of $2\frac{1}{2}$ tons of matte. The matte is broken by sledges to pass through the grizzlies; when the car has been filled it is drawn up a short inclined track, by a Turnbull electrically-operated hoist, into a standard box-car for shipment. This hoist is housed in a small building outside the matte-shed and on the opposite side of the standard-gauge track on which the box-car stands. The controller for the hoist is inside the matte-shed and close to the loading-point, which enables the operator to see the small car from the time it leaves the loading-pocket until it is drawn into the box-car.

IMPORTS of antimony into the United States showed an increase of about 76% in quantity and 68% in value in 1920, as compared with 1919, according to a U. S. Geological Survey report. Imports of metal rose 75%, owing to increased shipments from China and England; those from China increased 175%. Large quantities of antimonial lead are imported into the United States as type metal. The United States also uses annually about 2100 tons of virgin antimony contained in domestic antimonial lead and 3500 tons of secondary antimony recovered from old alloys, scrap, and dross.

*Abstracted from a bulletin of the Canadian Institute of Mining and Metallurgy.

REVIEW OF MINING

ACCUMULATION OF SCRAP-BRASS NEARLY CONSUMED —WILL HELP COPPER

A final clean-up of stocks of brass scrap has been taking place both here and abroad during recent months. For many months these holdings had a direct and detrimental effect on the copper market. However, the supplies of this kind of material fit for re-utilization at first-class manufacturing plants have decreased greatly since July. Producers and consumers were specially interested in the recent sale of British government holdings of brass-scrap to important financial interests. According to London advices the quantity of scrap metal disposed of was approximately 140,000 tons. The price at which the material was bought in was £24 per ton.

The price quoted was considered low. It appears that the material involved included, besides cartridge cases, all other classes of brass-scrap, some of a very inferior kind. The bulk of the material was not 70-30 mixture, but the commoner brass of 60-40 mixture. The 70-30 material is being gradually used up, but the 60-40 is a drug on the market. The syndicate which bought this material had to pay cash for the stuff as it lies in the various depots. Reputable manufacturers of metal products will not run the risk of using a poor quality of scrap alloys. They require clean high-grade metal in order to avoid dirty and defective finished products.

ANACONDA COMPANY SUED FOR \$100,000

Suit for \$100,000 in alleged unpaid Federal taxes plus penalties totaling about 130% of that sum, was filed in United States district court in New York recently against twenty-four former directors of the seven mining corporations absorbed in 1910 by the Anaconda Copper Mining Co. The complaint alleges the directors failed to report in 1909 on profits of \$9,509,963 as required by the corporation profits tax law of August 5, 1919. The defendants include John D. Ryan, William Rockefeller, H. H. Rogers, William G. Rockefeller, and Adolph Lewisohn.

The corporations named in the complaint were the Amalgamated Copper Co., Boston & Montana Con. Copper & Silver Mining Co., Butte & Boston Consolidated Mining Co., Butte Coalition Mining Co., Trenton Mining & Developing Co., Parrot Silver & Copper Co., and Washoe Copper Co.

UTAH CONSOLIDATED ACKNOWLEDGES DAMAGES OF \$1,079,734 DUE UTAH-APEX COMPANY

The United States Circuit Court of Appeals in Denver has confirmed the decision handed down by Judge Tillman H. Johnson of the District Court, Salt Lake City, in favor of the Utah-Apex Mining Co. in the litigation between that company and the Utah Consolidated Mining Co. There were six cases in all involving suits and counter suits. The Utah Consolidated in its suit claimed \$3,000,000 from Utah-Apex for alleged illegal extraction of ore from the Yampa limestone apexing in the former's territory. Utah-Apex claimed \$1,750,000 from Utah Consolidated for ore extracted in the Dana or Leadville vein apexing in the property of the former. In both of these suits Utah-Apex won a complete victory in the lower court and is now sustained in the higher

court. Under the court's decree Utah-Apex was awarded a verdict entitling it to damages from Utah Consolidated for illegal extraction of ore. The latter filed an accounting admitting that in the four years, from 1917 to 1920 inclusive, it had mined from Utah-Apex property ore valued at close to \$659,000 principal and interest. The Utah-Apex protested this accounting, and the Utah Consolidated has recently filed a revision in which the tonnage of lead ore extracted is given as 108,150 tons and the amount due Utah-Apex is acknowledged to be \$1,079,734.

MILLION-DOLLAR CONCENTRATOR FOR BRITANNIA COMPANY ON HOWE SOUND

The directors of the Britannia Mining & Smelting Co. have authorized the expenditure of \$1,000,000 for the construction of a 2500-ton concentrating plant, near the mines on Britannia Beach, to replace the one destroyed by fire last February. The crushing machinery has been ordered from the Taylor Engineering & Manufacturing Co., of Allentown, Pennsylvania, and will be shipped by way of the Panama Canal. It will consist of one 20 by 72-in. set of rolls, four 20 by 54-in. sets of rolls, and eighteen 7 by 10-ft. tube-mills. The construction of the plant will be supervised by Bradley, Bruff & Labarthe, of San Francisco.

NEW RAILROAD FOR NORTHERN ONTARIO WILL BE CONSTRUCTED

The Canadian Light Railway Construction Co., organized to build a railway to open the mining districts lying east and west of Swastika, has been reorganized and has taken over the charter of the Northern Light Railways. It will proceed at once with the construction of the road. Engineers are in the field and preliminary work is under way with a view to pushing construction as far as possible before severe weather sets in. The line will be of standard-gauge; light rails will be laid at the outset, which can be replaced later with heavier steel should the traffic require it.

MINE OPERATORS PLAN TO HELP REVIVE FOREIGN COMMERCE

Representatives of metal-, coal-, and oil-mining industries, appointed by the American Mining Congress, conferred recently with Secretary Hoover. The Secretary referred to the assistance, in reviving American foreign commerce, which mineral producers could give through co-operation with American shipowners, and a sub-committee consisting of T. H. Watkins, representing coal, George S. Davidson, representing oil, and Bulkeley Wells and B. B. Tflayer, representing copper, was appointed to join with representatives of other exporting interests in conference with steamship owners looking to plans to assist. This committee will formulate recommendations to be considered by the general committee. Assurance was given the Secretary of the co-operative assistance of the mining industries.

POSITION OF ZINC IMPROVES

There has been improvement in the statistical and trade position of zinc during the past three months, yet it has in no sense been as sensational as New York reports would

lead one to believe. There are in surplus stocks in this country approximately 71,000 tons. This compares with 91,000 tons on the first of July, the highest point ever known, and a normal surplus around 30,000. Recent advances had the surplus drawn down to 40,000 tons and this was 10,000 tons above the normal, according to the 'Boston News Bureau'.

In August and September the visible surplus was reduced 5000 tons in each month. October was a period of relatively brisk business and stocks were cut 10,000 tons, leaving the total at the end of that month at approximately 71,000 tons, and it is not at all improbable that at the end of the current month another cut will have been made. Production in this country is at present running between 14,000 and 14,500 tons of zinc per month, against a normal output of 25,000 to 30,000 tons. There has been a substantial demand from the steel industries and galvanizers, and this improvement in the statistical position is all the more striking when it is remembered that today foreign zinc smelters are able to ship their product to this country and meet domestic competition. Butte & Superior recently advanced to 17½, up 4 from its recent low, and American Zinc has sold at 11, as compared with low of 8. The preferred sold at 35, a 10-point advance from its low point.

GREENE-CANANEA COMPANY IS SELLING COPPER RAPIDLY; ANACONDA INTERESTS ACQUIRE STOCK

The Greene-Cananea Copper Co. has materially lightened its holdings of unsold copper recently. At the close of last year the company had a considerable tonnage of metal on hand in addition to the 18,400,000 lb. it had pledged with the Copper Export Association in the latter's 400,000,000-lb. pool. Most of the copper it was carrying itself has been sold. Regardless of this lightening of the inventory load, however, it is not the intention of Greene-Cananea officials to resume operations right away. The company is exceptionally well entrenched in liquid assets, having had at the close of last year nearly \$7,000,000 over and above all liabilities. This is equivalent to almost \$12 per share on the 500,000 shares of Greene outstanding—virtually 50% of the present selling price of the stock. The steadiness of the shares in the last few months, or since the August lows, has been noteworthy. No small amount of the buying has been traceable to interests identified with the Anaconda Copper Co., and while the latter is a holder of record of 59,600 shares of Greene-Cananea, its actual ownership is thought to be very much in excess of this.

TINTIC STANDARD MILL IS GIVING SATISFACTION

The chloridizing-leaching plant of the Tintic Standard Mining Co., east of Eureka, Utah, is treating in the neighborhood of 160 tons daily. It is expected that two more roasting-furnaces, started several weeks ago, will be completed and in operation in December, bringing the total number up to nine and increasing the mill's capacity to a considerable extent.

Some time ago the smelters forced the Standard and other Tintic mines to reduce shipments. This order made a big difference in the output from the East Tintic property, but it is believed that it will be only a short time until the mine is able to place a much larger amount of ore on the market. E. J. Raddatz, the manager, is quoted as saying: "We have been shipping our product twice each month and getting out 50,000 oz. of silver every 30 days. It is quite certain that a large amount of silver, perhaps over 60,000 oz., will be marketed during the present month. I am thoroughly pleased with the milling operations and wish to say that the disappointments in connection with the plant have been of a trifling nature. The mill is sure to be a big factor in the growth and development of the Tintic Standard

mine. We are still experimenting on our lead-saving apparatus."

NORTHWEST MINING ASSOCIATION OPPOSES NEW MINING LEGISLATION

The following resolution was passed by the Northwest Mining Association, at a special meeting on November 19, 1921:

Whereas a bill to revise, amend, and codify the laws of the United States, relating to the location of mining claims on the public domain, is now before the 67th Congress and known as H. R. 7736; and

Whereas the purposes and probable effects of this bill, if enacted, have been carefully studied by competent committees of this Association and have been adversely reported upon; and

Whereas the existing Federal Mining Laws are now well and generally understood, as interpreted by the courts in the last 49 years, and have not proved sufficiently defective to require drastic revision, now therefore be it

Resolved, That the Northwest Mining Association, representing mining interests in the States of Montana, Idaho, Washington, and Oregon, at a regular meeting in Spokane, Washington, November 19, 1921, does hereby respectfully protest the passage of this bill on the ground that it is not competent to improve present mining conditions, but that, on the other hand, it would doubtless prove both burdensome and intolerable in several respects and make confusion worse confounded, as shown by the attached analysis which is hereby made a part hereof. And be it further

Resolved, That this Association believes that no legislation should be enacted to further handicap the mining industry at this time, but that it should be permitted to recover from its present depression under the old and well-known statutes.

Also, that copies of this resolution and the analysis of H. R. 7736 be sent to each Senator and Representative of this region and to the chairmen of the Senate and House Committees on Mines and Mining, with an urgent request for their careful consideration.

The undersigned hereby certify that the above is correct:

G. B. DENNIS, President.
F. C. Barley, Secretary.

ARIZONA

Bisbee.—Messrs. Medigovich and Lutich have opened a good-sized body of rich ore on the Wakefield Silver-Gold property in the Hauchuca mountains. The lessees have erected a 5-ton concentrator and are saving 90% of the metal in the high-grade ore. Operations will probably continue through the winter.

Several thousand tons of the best ore known for years in the Bisbee district is reported ready for stoping in the Southwest claims of the Copper Queen Branch. The ground is near the upper end of the limestone and the Southwest workings are said to be close to the quartzite bottom within which no ore has been found. In the same section, around the Glory Hole, were the original workings of the camp, the only point where the copper ore was visible on the surface. Nearly all the slag of the old Copper Queen smelter has been used as flux in the company's smelter at Douglas, incidentally contributing about 5% of copper that had been left by the imperfect smelting operations of pioneer days. The rest is to go to Douglas when the furnaces are again heated. Much of the old dump-site is to be included in the scope of the steam-shovel operations that are to start at Sacramento Hill.

Douglas.—Landowners are making complaint of damage they say is done to crops by the smoke of the Copper Queen and Calumet & Arizona smelters. At a conference held be-

tween company officials and representatives of the land-owners there was indication of willingness on the part of both sides to adjust differences without litigation. A similar dispute taken to the courts from the Verde valley near Jerome gave the former plaintiffs a verdict of \$1 and costs.

Jerome.—The Shannon Copper Co. has discontinued development work on its Yaeger and Gleeson properties. During the course of exploration, 1000 tons of ore assaying 40% copper was mined and is now ready for smelting when operations are resumed.

Katherine.—James F. Collins is in charge of development of the Big Four group, with W. W. Wishon, of Searchlight, as consulting engineer. A development fund of \$30,000 is available. The property is near the Gold Chain. The company's main vein is said to sample from \$2 to \$5 per ton across 10 ft.—The Adams property, a mile from the Gold Chain and on the same vein, has erected a surface plant, moved from near Oatman. At 50 ft., two feet of quartz is said to average \$30 in gold.

Kingman.—The Tom Reed company, rather than deplete its high-grade ores, is planning methods for more economical working of the immense quantity of developed ore of medium or low grade. Some miners have been laid-off. There is hope that the mill may be continued at full capacity by taking about 100 tons per day of custom ores, on a basis of \$2 per ton cost, with payment for 95% of the gold value and 80% of the silver. The Gold Ore is understood to be contracting for the handling of 50 tons per day, and the United American and Telluride, near-by properties, also have large quantities of available milling ore. Most of the high-grade Tom Reed ore is being taken from the Aztec section, and trammed to the Ben Harrison shaft.

The Oatman United company is developing a 3-ft. vein said to average \$20 for a distance of 200 ft. Drilling has shown the presence of ore much deeper than the drift-level at 600 ft.—The United Eastern is reported to have cut its vein 200 ft. from the 850-ft. station by means of a diamond-drill. Development work is to be started soon on the ground lately purchased from the Big Jim Co. On this ground, ore was developed on the 600-ft. level, the deepest working.—A stringer of rich silver ore has been cut in a tunnel intended to develop water for irrigation from flooded workings in the old Silver King mine, 15 miles east of Kingman. Operations were suspended years ago when the vein faulted. Now there is belief that the stringer points the way to a continuation of the main orebody. The new ore assays up to \$700 per ton.

CALIFORNIA

Angels Camp.—J. B. Cella, of New York, J. B. Demaria, and Dante Foresti are reported to have purchased a large block of stock in the Triple Lode gold mine. With the money thus secured development of the property will be rushed.

Downieville.—A. T. Hathaway and E. L. Cleveland have taken an option and lease on the Oxford mine near here. The terms of the contract have not been disclosed. The Oxford is owned by a corporation headed by H. H. Meyer and E. L. Case. It is a quartz-gold property and has yielded well at various times.

Etna Mills.—Operations have been resumed at the Cub Bear mine by the Siskiyou Syndicate, and the five-stamp mill formerly operated at the Advance group is being moved to the property. Gold ore of good grade has been opened. The property was closed during the War.—Good ore is reported exposed in the Highland mine, and the management is completing arrangements for a steady output throughout the winter. The Highland has long been a noted producer of high-grade ore.—Rehabilitation of the old Black Bear group is proceeding, and the dump ores are being milled.

Sonora. The Springfield tunnel has been connected with the old shaft after 12 years of work under the direction of John S. Cademartori. The task of driving the drain-tunnel has cost about \$500,000. Almost fabulous gold ore was found in the bottom of the old shaft before the miners were driven out by water. Four large steam pumps were unable to check the flow, so work was abandoned and the long tunnel was commenced.

Sutter Creek.—Two hundred feet of shaft-sinking at the Central Eureka mine has been completed and timbers are in place. The bottom of the shaft is in greenstone. It is 4194 ft. from the collar of the shaft to the bottom. Some shaft-bulkheads are to be taken out, and the main skip-tracks extended about 200 ft., after which the miners will start to cut the 4100-ft. station and the ore-bins beneath it. Albion S. Howe, superintendent, says that this will be done as rapidly as possible. A new transformer-house has been erected. The new hoist building is nearly completed and work of

Cripple Creek, Colorado, and Vicinity

assembling the hoisting machinery is well advanced. When the ore-bins, skip-tracks, and hoisting machinery are installed, the production of ore on the lowest level of the mine will be begun. The mine now is one of the deepest on the Mother Lode.

COLORADO

Aspen.—The Hurricane Mining Co. operating its own and leased properties extending from the Hurricane and Climax to the north and to Castle Creek, south, has opened a new vein on the Eteetera claim. The 'paystreak', two feet wide, samples 5 to 15% lead and 10 oz. silver; it is gaining in width and richness as the drift is extended. The breast of the tunnel is nearing the point where the orebody exposed in the upper tunnel should be cut. The new tunnel will drain the upper workings and afford 150 ft. of backs.

Central City.—The Comet tunnel, near the Rara Avis mine, has been leased and bonded to Illinois and Nebraska operators, who have opened a 6-in. streak of ore sampling \$45 per ton.

Creede.—Lessees on the New York have opened a big body

of mill-ore between the 9th and 10th levels and have commenced shipments. The Manitoba is producing good smelting ore and the owners and operators are making weekly shipments to the Leadville smelter regularly.

A shipment of \$50 ore was made to the A. V. smelter at Leadville by lessees on the Ethel mine recently.—The Wabash M. & P. Co. is shipping regular weekly 5-car consignments of ore to Leadville; with a lower freight-rate production and shipments would be increased.

Cripple Creek.—The Cresson company continues heavy production: 8 to 18 cars averaging 35 tons to the car are shipped daily. This ore averages \$12 to \$15 as broken. The shares of the company made a big advance on the Colorado Springs Exchange and New York Curb market recently.

Increased tonnage is the order of the day at the Portland. The tonnage to the Independence mill has been increased 50% while the treatment cost has been lowered. Perry O. Harrison has succeeded G. M. Taylor as manager. Thomas B. Crowe, mill manager for many years, has resigned and left the service of the company. Work also has been resumed at the Independence where the haulage tunnel is being extended 750 ft. to make possible the more economical handling of ores from the Battle Mountain mines.

Ouray.—Oil men of Colorado and Wyoming, with some capital, have formed the Welch-Worland Mines Syndicate and taken over the mines and milling plant originally owned by the Wanakah Mining Co., and more recently by the Union Mining & Milling Co., under a bond and lease covering a nine-year term. The property is credited with producing in excess of \$1,000,000 in gold, silver, and copper ore. Modern machinery has been ordered to re-equip the mill and mine, and development is planned.—Lessees on the No. 1 and No. 2 levels of the Barstow mine are producing. Shipments will be made soon.—A new trail is under construction to the Hidden Treasure and shipments of three cars weekly will be maintained during the winter.

Silverton.—The Little Nation Mining Co. has increased its operating force and will continue work through the winter. A raise has been started to connect the Royal Charter and Little Nation levels proving the continuity of the orebody. Good mill-ore is opened for the entire distance of a 1000-ft. drift. The ore-streak is 12 to 18 in. wide carrying both lead and silver. The Royal Charter level, about 250 ft. below the Little Nation level, has been extended 1200 ft.; the continuation of the several ore-shoots from the level above has been proved.

IDAHO

Coeur d'Alene.—According to reports the Day interests intend to resume the first of the year the operation of their mines in this region. These include both the Hercules and the Tamarack & Custer, two of the largest lead-silver mines in the United States.—Resumption of operations by the Nabob Consolidated company is predicted by Charles H. Fisher, recently elected as one of the new directors of the company. A recent court order gives Spokane and Coeur d'Alene men control of the property and they have elected a new board including E. J. Lippert, Charles H. Fisher, J. E. Codd, and A. W. Codd, all of Spokane. A. E. McCarthy, the fifth director, is a resident of Coeur d'Alene.—The new cross-cut on the Jim Blaine group has been driven 220 ft., according to reports at hand. It has penetrated a blind vein 21 ft. without reaching the wall. The vein is reported to contain 3% lead, and 2 oz. silver per ton. The property consists of 27 claims opposite the Nabob mill on Pine creek. Additional men have been employed.

MICHIGAN

Houghton.—Sinking will be resumed in the New Baltic shaft of Arcadian Consolidated early in December. It has

been virtually decided to continue the shaft, now bottomed at the 942-ft. level, to a depth of 1060 ft., corresponding with the 1050-ft. level of the New Arcadian shaft which is bottomed at 1850 ft. It is expected the objective will have been reached by February 1. A drift southward to connect with the New Arcadian shaft then will be driven, paralleling the south drift from the 9th level. It is primarily to drive this new drift that the New Baltic shaft will be lowered for it will provide the means and opportunity for a closer checking of the ground and furnish the desired geological information necessary to an intelligent opening of the territory between the two shafts. An additional small force of men will be employed for the sinking operations. The company is well supplied with machinery and practically all material for the performing of this work. It has adequate hoisting facilities, drills, rails, piping, and pumps, lacking only the necessary timber. The vein is close to the shaft and the shaft will go down just under the lode.

Throughout the years that copper flourished and the Lake district prospered accordingly, having no thought of any possible setbacks, little or nothing was heard of diversified industries here. But this subject has been foremost in the copper country's mind since the depression in the copper market forced the majority of the mines to close. There appears to be a widespread belief that copper could be fabricated here, and there is a marked disposition to look to the mining companies to get into the manufacturing field. But it is apparent the companies are not very keen about it and it would appear they would rather continue as they have been doing, mining copper and taking their chances in the open market. Once operations are resumed, however, it is unlikely any great surplus of metal ever will be accumulated again.

With the return of normal conditions in the metal market Wolverine no doubt will be encouraged to explore amygdaloid formations found several years ago on the 13th level, west, and the 22nd level, east. The showing in these veins for the short distance they were drifted into warrants further investigation. Wolverine's yield continues at 14.5 lb. per ton, refined. Pillar mining is being conducted on the 35th, 36th, and 37th levels of No. 4 shaft, while regular mining, such as widening of stopes and drifts to the hanging and foot-walls, also is under way in the lower levels.

It is estimated there are 12,000,000 tons of sand in the Tamarack conglomerate tailing in Torch lake, assaying 12½ lb. of copper to the ton. Calumet & Hecla plans to complete the reclamation plant there next summer and the recovery of this metal then will begin. While the deposit is not as extensive or as rich as that of Calumet & Hecla proper, the copper can be recovered at low cost and the plant investment will yield a large return. The Calumet & Hecla deposit originally contained 40,000,000 tons, running as high as 14½ lb. of copper to the ton. In 1920, the Calumet & Hecla tailing assayed 13.1 lb. per ton and of this amount 10½ lb. was recovered. A total of 14,138,240 lb. was produced, at a cost of 6.6c. per pound, exclusive of smelting and selling expense. This cost was high on account of the abnormal price of coal and high cost of labor and supplies. It compares with a normal cost of 4½ to 5c. per pound. In the few years the Calumet & Hecla reclamation plant has operated it has recovered 48,537,488 lb. of copper. It is estimated the remaining sand carries over 450,000,000 lb. of metal. There was a time when the idea of recovering any copper from the sand was scoffed at, but the results have fully justified the hopes of the company.

MONTANA

Butte.—The North Butte company has approximately 14,000,000 lb. of unsold copper on hand but the directors instructed the selling agents recently to suspend sales until further notice. Development of the Edith May vein on the

3400- and 3600-ft. levels from the Granite Mountain shaft is progressing satisfactorily.—The Colorado mine of the Davis-Daly company has been shut-down, but the pumps are in operation and foremen and other officials are being retained on the payroll. The company's Hibernia mine continues to operate regularly.

Wise River. Operations have been commenced at the Boston-Montana mill, following the completion of connection with the main electric-transmission line of the Montana Power Co. Electric energy is now available for the treatment of 750 tons of ore per day, as planned for the initial unit of the mill. The plant is going through the 'breaking-in' process, and regular production should start soon.

NEVADA

Candelaria.—Plans for the erection of a 300-ton cyanide plant for the Candelaria Mines Co. are complete. The mill will be built near the portal of No. 11 tunnel below the railroad grade. The Candelaria company owns the old Ar-

Hill mine in the Railroad Springs district. The vein is 20 ft. wide and can be mined to yield some shipping ore.

Rochester. The Rochester Silver Corporation, during the first half of November, milled 155 tons of ore per day, having a gold content of 0.137 oz. and 12.23 oz. silver. During October 92.8% of the gold and 84.7% of the silver in the ore was recovered in the company's cyanide plant.

Tonopah.—The Gold Zone Co. has confirmed reports of important developments on the 500-ft. level. The vein was first entered early in October, 16 ft. from the boundary line of the Tonopah Divide, and is said to have been proved for over 200 ft. by raises from the 500-ft. level. Shipments to Tonopah mills have begun and work has been started on the 300-ft. level to tap the vein at this point.

NEW MEXICO

Las Cruces.—Gold has been discovered recently on the south-west slope of the San Mateo mountains, 115 miles north-west of here, according to the statement of A. H.

Hauling Mine-Timbers in the Coeur d'Alene Region

gentum and Mount Diablo mines and the Lucky Hill property that is on the Mount Diablo vein; \$610,000 of assured ore that will assay \$15 mostly in silver constitutes the ore-reserve to date.

Carson City.—A through joint rate on ore from Plumas county, California, to the Thompson smelter near Wabuska has been ordered by the Interstate Commerce Commission. Heretofore the rate charged was a combination of local rates over three roads; the consequence was that the 600-mile haul from the Engels mine to the smelters in Utah was cheaper than the 210-mile haul to Wabuska. According to the new schedule the freight from Plumas county to Wabuska will vary from \$2.83 to \$5.36 for ore valued at from \$20 to \$100. This compares with a rate of \$5.35 per ton for \$100 ore to the Utah smelters.

Ely.—Following an examination by Raymond G. Guyer and S. M. Soupcoff the Boston & Ely company has increased its working force. The shaft has reached a depth of 100 ft. and cross-cuts will now be driven east and west in the limonite. It is reported that 20,000 tons of 6% copper ore has been developed.

Goldfield.—It is stated that the Goldfield Development Co. has entered an ore-shoot at a depth of 300 ft. in the Gold

Reynolds, of El Paso, made in the 'El Paso Herald'. He is quoted as saying: "It is a camp that only mining men or prospectors with \$500 to \$1500, which they can afford to spend, should investigate. It is no place to start a rush or a boom by a lot of poor people expecting to make money quickly and easily, for it is, of necessity, not that kind of a camp. With that reservation and caution, I do not hesitate to say that in my 40 years of mining experience, during which I have seen a good many gold camps, I have never seen in a new camp a larger or better showing of gold. I have about five pounds of specimens of the newly discovered ore showing free gold. It is from a stringer 3 ft. wide, at the bottom of a 20-ft. shaft in a 30-ft. lode that all pans gold. Conditions of the locality of the new camp are favorable to economic operation of mines and mills. The nearest stores and postoffices to the camp are at Monticello, 6 miles, and Cuchillo, 12 miles. Both are in Socorro county. The Elephant Butte irrigation dam and lake are in sight of the camp. There is plenty of wood and mountain water. Good roads lead to the camp."

UTAH

Big Cottonwood Canyon.—Bonanza ore has been found in the Woodlawn mine. At first it was but 3 in. thick; it is

now 6 in., and W. J. Lawrence, manager, believes that the streak will prove to be a lead to an ore-shoot in the limo stratum which the lowest level in the mine—the 700—is approaching. Two tons of ore has been shipped, which gave smelter returns of \$2.83 in gold, 405.1 oz. in silver, 2.09% copper, 7.35% lead, and 9% iron.

Eureka.—Directors of the Eureka Hill Mining Co. have declared a dividend of \$1 per share, which will call for the disbursement of \$10,000. This is the first dividend to be paid in two years. The Eureka Hill is a unique property. It has been a steady producer for 51 years, has never levied an assessment, and has paid more than \$2,250,000 in dividends. The 10,000 shares of stock are owned by four people, only one of whom, Moylan C. Fox, resides in Utah. The company owns 29 acres in the heart of this district, has been opened by 35 miles of workings, and is one of the richest mines ever discovered in Utah. During recent years the revenue has been derived from royalties received from lessees and money received from the sale of water of which the company has an excessive supply.

Engineers for the Chief Consolidated Mining Co. are making an examination and survey of the Eureka Lily property, preparatory to beginning development work. Plans for development at the Grand Central mine are being made by Paul Hillsdale, who recently took an option on the property. While the mine is being re-surveyed and mapped, Hillsdale will continue to permit lessees to work. The scale of royalties will be the same as under the old management; from 25% on the lower-grade ores, up to 75% on ore carrying \$200 per ton and over. W. J. Coombs, who has been connected with the Grand Central for many years, will act as lease-boss.

F. A. Hebbard, a geologist formerly connected with a large oil company in California, has taken a lease on the talc deposits of the Dragon mine. Within a short time Mr. Hebbard expects to be shipping 500 tons of fuller's earth per month. This tonnage has been contracted by one of the large oil companies on the Pacific coast. Fuller's earth, used in the refining of mineral oils, is said to be worth \$20 to \$25 per ton, f.o.b. Pacific coast points. Hebbard states that the oil industry last year consumed 300,000 tons of the material, whereas in 1890 the consumption was but 20,000 tons. The local product is said to be of a higher grade than the Florida deposits, which heretofore have been the main source of supply in the United States.

Ore shipments from this district for the week ending November 19 totaled 167 carloads. The Chief Consolidated shipped 46 cars; Tintic Standard, 46; Victoria, 17; Dragon, 14; Iron Blossom, 10; Eagle & Blue Bell, 8; Swansea, 4; Centennial-Eureka, 5; Grand Central, 3; Gemini, 2; Empire Mines, 2; Bullion-Beck, 2; Mammoth, 1; Sunbeam, 1; and Eureka Mines, 1. Shipments the previous week totaled 165 carloads.

Officials of the North Standard Mining Co. are taking a keen interest in the sinking of the Water Lily shaft by the Chief Consolidated Mining Co. This shaft is but 600 ft. from the south boundary of the North Standard's property, and the results obtained by the Chief Consolidated in the way of development work in that vicinity will have a bearing on future exploratory work in the North Standard. Recent developments on the 500-ft. and 1100-ft. levels have been encouraging.

Park City.—Shipments of ore from this district for the week ending November 19 totaled 2279 tons, as against 1962 tons the preceding week. The Silver King Coalition shipped 948 tons; Judge allied companies, 943; Ontario, 385.

Recent development work at the Park-Utah property has been of such an encouraging nature that numerous claims have been taken up by local residents and mining companies

in the territory to the east of the Ontario dike, a part of the district that has never been thoroughly explored.

Salt Lake City.—The slogan 'Buy Something Made of Copper' has been featured extensively in Utah recently. The Salt Lake Commercial Club adopted a resolution, calling upon all of its members to give the fullest publicity to the slogan, as well as to practice it. The moving-picture theatres have joined in the movement, using slides reading: "Buy Something Made of Copper and Help to Re-open Utah's Copper Mines".

In the case of *Nikolas Pappas v. the American Smelting & Refining Co.* for alleged damage to the plaintiff's bakery shop and home at Murray, caused by smoke from the slag dump, a verdict in favor of the smelting company was rendered on November 23. This is the first smelter smoke case to be heard in Utah in a number of months.

The Bingham & Garfield Railway Co. and the Salt Lake Route have been given permission by the Public Utilities Commission to discontinue the passenger train operated between Salt Lake City and Bingham. The railway companies submitted a statement to the Commission that they were losing \$1000 per month in operating this train. Since the closing down of the Utah Consolidated, Utah Apex, and Utah Copper companies last spring, Bingham has lost much of its population. It is stated that the present population of the camp is about 2500, as against 8000 in 1918. An auto-bus service is operated between Salt Lake City and Bingham, and this line gets practically all of the passenger and express business.

A recent compilation of figures submitted by the State Board of Equalization reveals interesting information concerning metal mining in Utah during 1920. The total operating costs of the metal-mining companies that year were \$34,893,412. Of this amount, the cost of mining and development, including labor, powder, timber, drill-steel, power, etc., was \$13,324,629; milling and smelting expense, \$17,559,727; freight on ore and concentrates, \$2,850,657; while construction expenditures at mines, mills, and smelters totaled \$1,158,399. Another interesting feature of the report is that the metal mines of the State last year supplied 45% of the total tonnage of intra-state business handled by the railways. Mining is the most important industry in Utah; when the mines prosper, the State prospers.

WASHINGTON

Spokane.—Adolf Kunz, of Chicago, president of the American Minerals Production Co., which operates large magnesite properties at Valley, 50 miles north of here, had the following to say regarding the tariff on magnesite during a recent visit:

"The tariff bill, which would give a tariff of \$15 a ton on magnesite, has passed the House and is now being considered by the Finance Committee of the Senate. We hope for and should receive a favorable report. So far as we know all of the Western Senators and Representatives are in favor of such a tariff. We do not ask that foreign magnesite be shut-out, but we do ask for a tariff that will enable us to compete, which we can not now do. This country needed and used our magnesite during the War, while the Austrian magnesite, now being shipped in, was used to make bullets for use against us. We do not believe that this country should give all its trade to Austria.

"We have done much experimenting with plastic magnesite for use in building operations, as stucco, for flooring, and other similar uses. We have met with a great deal of success and can deliver a uniform product, lack of which used to be the main objection to magnesite. We are just completing two new kilns and are shipping some magnesite for building purposes. With the tariff in effect so that we have a chance at the refractories business we are in position to ship larger quantities and employ more men."

BRITISH COLUMBIA

Alice Arm.—The Dolly Varden mine was shut-down on November 7 for an indefinite period. The Taylor Mining Co. has not repaired the wash-outs and damage to the foundations of some of the bridges, caused by the floods of last month, and consequently it is impossible to take supplies to the property or bring ore from it. It is understood that the Taylor company has been trying to get additional money into the concern, to finance much-needed repairs, development of the mine, and the erection of a concentrating plant. Recently J. A. Bancroft, assistant manager of the Granby Consolidated company, examined the mine, making the trip on a hand-car with members of the Taylor company and others; on the return journey the car left the tracks and all were precipitated into the Kitsault river. Fortunately, none was any the worse for the adventure. The cessation of the operation of the railway is a serious handicap to other mines and prospects at the head of the Kitsault river.

Cranbrook.—The Gamble Mining Co. held its annual general meeting on November 9, when the manager stated that

ran from \$30 to \$40 per ton. Some 15 tons of the shipping ore has been sacked, and will be sent to the smelter as soon as the condition of the snow allows sledding. — William Fraser reports the discovery of a new 8-ft. vein, well impregnated with gray copper, on his property, in the Marmot River district.

Vancouver.—A cable from London was received at the Granby Consolidated M. S. & P. Co. office on November 17, announcing that the Privy Council had rendered decisions in favor of the company in all the four cases that had been tried. These decisions vest the Cassidy colliery securely with the Granby company. The decisions are of considerable importance, apart from the fact that the Granby has expended some two and a quarter million dollars in the purchase and equipment of the colliery.

MEXICO

El Tigre.—John Hohstadt is doing a large amount of development work on his claims in the Pihares de Teres district north of here. William Hudson, the contractor, is

Camp at the Dolly Varden Mine

at the time of the shut-down, necessitated by lack of water, good pay-dirt had been found; now, with ample water assured, the outlook for a profitable season next year is bright. John Taylor was elected president and general manager.

Hudson's Hope.—Detroit capitalists have secured claims along 20 miles of the upper Peace river, where, it is said, some rich ground has been proved. The owners propose to put a dredge on the river next spring.

Pentleton.—A find of rich silver ore has been made at the Sally mine, particulars and extent of which, however, are not yet to hand. The Sally, which is operated by the Wallace Mountain Mines, Ltd., has been producing ore running between 300 and 400 oz. silver per ton; last year it shipped ore to the value of \$80,000 to Trail.

Stewart.—W. R. Tonkin, president and general manager for the Fish Creek Mining Co., has gone to Seattle for the winter, and expects to arrange for the erection of a concentrating and compressor plant at the mine in the spring. Tonkin reports that rich ore has been struck on the Olympia claim in a raise that was started to connect No. 1 and No. 2 tunnels. It is believed that the shoot is the same as that found on the surface and in the No. 2 tunnel. On the surface the ore-shoot was uncovered for a length of 600 ft.; it averaged 5 ft. in width, and one-third of it was shipping ore, ranging from \$300 to \$400 per ton, while the remainder

driving a tunnel north of La Bota canyon in the hope of striking the Carabinas vein which has been one of the best producers in this district. A vein 10 ft. wide of lead-zinc ore carrying 35 oz. silver was found on the southern part of Hohstadt's ground, but no attempt has been made to mine this as yet.

George S. Solomon of Bisbee and partners have taken up a group of claims reaching from the Santa Isabel north of La Bota canyon, to the Santa Maria claim of the El Tigre Co. The claims include La Bota, La Mina Suerte, and La Suerte Segunde. Development work will be started immediately on La Bota.

Moctezuma.—The Progreso Silver Mining Co. has been running one shift continuously for several months in its cyanide plant, on ore from the dumps. Approximately 10,000 oz. of silver bullion containing some gold is produced per month.

ONTARIO

Cobalt.—The question of operating the Temiskaming mine under a leasing system is under consideration. The matter was discussed in official circles on former occasions, but the possibilities of the company operating the property profitably on its own account discouraged the scheme. Now, however, with the mine closed down, it is believed the underground workings could be divided into sections of limited size and

leased to good advantage on a royalty basis. It has just been learned that a group of Cobalt miners are preparing a tender to participate in leases on the mine provided the directors consider the plan favorably.

The original property of the La Rose Consolidated, which was flooded recently by a cave-in of rock, permitting the water flowing from Cobalt lake to enter the workings, will probably never be unwatered. The mine is flooded completely, and a considerable tonnage of low-grade ore as well as a limited amount of high-grade has probably been lost. The company continues to operate its Violet, University, and Princess properties with success, and is producing from 1000 to 1500 oz. of silver daily.

Kirkland Lake.—The Lake Shore during October established a new high record by the treatment of 2015 tons of ore with a recovery of \$51,302, averaging \$25.46 per ton. The mill ran 97.98% of possible running time.

A special meeting of the shareholders of the King Kirkland will be held on November 28 to consider proposals to increase the capitalization from 2,500,000 to 5,000,000 shares and to purchase the Ferguson claims in the Larder Lake district comprising 80 acres for 45,000 shares.

Porcupine.—The directors of the McIntyre have decided to proceed immediately with the installation of additional equipment, which it is calculated will increase the capacity of the mill from 550 tons daily to 800 tons. Action has been delayed for some time on account of the occurrence of carbon in the ore from the lower levels rendering it difficult of treatment by the ordinary methods, but this obstacle has now been satisfactorily overcome. The new equipment will be a separate unit of 250 tons capacity designed for the treatment of the carbonaceous ores by a special process of oil-flotation. The work will commence immediately so as to have the new unit ready for operation in March. The main shaft has now reached a depth of 1875 ft., where a station is being cut preparatory to opening levels at 1625, 1750, and 1875 feet.

At the property of the Union Mining Corporation, about 30 miles south-west of the producing area of the camp, a shaft is down 300 ft. and lateral work is being done at the 150- and 300-ft. levels. Diamond-drilling will be undertaken to explore the property at a lower depth.

The Nipissing, of Cobalt, has resumed diamond-drilling on the Rochester immediately adjoining the Hollinger. Assay-returns from previous drilling are understood to have been favorable.

YUKON TERRITORY

Dawson.—George Black, one of the candidates for Yukon in the coming Federal election, has just returned from a trip to Mayo and Keno Hill; he reports great activity at the latter place. The Alaska Treadwell interests are sinking two 300-ft. shafts, which are to be connected by four levels. The Yukon Gold Co. has opened a new lode, the ore in which is running from 300 to 500 oz. in silver. A rich strike has been made on Galena hill, about a mile from Keno Hill, and sixty new claims have been staked. Altogether 1500 claims have been staked on Keno hill. About 600 men are employed at the camp, and the hauling of ore to Mayo Landing has commenced. It is expected that fully 6000 tons will be shipped from there next spring. A telephone line connecting Keno Hill with Mayo has just been completed.

—There has been a small stampede from Dawson and adjoining creeks to Allgold creek, a tributary of Flat creek. The creek has been prospected before, but most of the leases have been abandoned and have reverted to the Crown. Duncan Michle, who has been prospecting on Allgold creek for seven years, recently struck good ground, much of which, it is stated, is running up to \$15 per pan. The gold is 'nuggety' and coarse. It was this discovery that caused the stampede.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

George H. Garrey is at Tonopah.

C. K. Leth was in New York last week.

Norman Stines spent Thanksgiving at Seattle.

Charles Jania is on his way from San Francisco to New York.

Frank L. Sizer has returned to San Francisco from Elko, Nevada.

A. W. Fahrenwald has returned to Moscow, Idaho, from Nevada.

Arthur Notman has moved from New York City to Bisbee, Arizona.

Etienne A. Ritter has moved from Oatman, Arizona, to Denver, Colorado.

A. G. McGregor has been elected president of the Bisbee Chamber of Commerce.

Reginald E. Hore has been appointed editor of the 'Canadian Mining Journal'.

J. P. Benson, recently at San Juan de Lima, in Nicaragua, is now at Berkeley, California.

Norman D. Lindsley has moved from Dos Cabezas, Arizona, to Lakeside, Washington.

A. Law Voge, chemical engineer, of New York City, has been in Nevada and is now here.

Persifer G. Spilsbury, who now resides at Phoenix, has been recently at Clifton, Arizona.

Arthur R. Weigall, of the Tul Mi Chung company, at Seoul, Korea, is in San Francisco.

Erick K. Craig, recently at Medellin, Colombia, South America, is at Piedmont, California.

J. B. Tyrrell has been examining a group of mines in the Cariboo district of British Columbia.

J. E. White, of Santa Barbara, has been examining a group of claims at Randsburg, California.

William Forstner has returned from examining the old Niagara mine in Shasta county, California.

F. E. Dodge is vice-president and manager for the Protextol Corporation, Kenilworth, New Jersey.

Harry R. Bischoff has left the Coeur d'Alene region and is temporarily residing at St. Paul, Minnesota.

Walter J. Eaton has been appointed superintendent of the Smuggler-Union mine, at Telluride, Colorado.

C. T. Durell, who is now in the Natural Resources Division of the Treasury department, spent Thanksgiving in San Francisco.

Robert S. Lewis, Professor of Mining, is now at the University of Utah, in Salt Lake City, having returned from Los Angeles.

William J. Loring has returned from a week's trip through southern California on business in connection with his various enterprises.

Charles Bocking, manager for the Butte & Superior Mining Co., has returned to Butte after an absence of several weeks in New York.

C. P. Nichols, son of Horace G. Nichols, has graduated from the Royal School of Mines, London, and has joined the staff of the Burma Corporation at Namtu.

T. Nishikawa, of the Imperial University at Tokyo, has been visiting mining districts in Utah, accompanied by a party of friends. He will sail from San Francisco on the 'Tayo Maru' on December 5 for Yokohama.

THE METAL MARKET

METAL PRICES

San Francisco, November 29

EASTERN METAL MARKET

(By wire from New York)

November 28.—Copper is active and higher. Lead is quiet and firm. Zinc is quiet and steady.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 40 65 pence per ounce (925 fine), calculated at the normal rate of exchange.

RAILROAD BONDS ADVANCE STEADILY

After a steady advance, beginning in mid-summer this year, the bond market suddenly developed a most sensational upward movement on news of the re-discount rate of the New York Reserve Bank from 5 to 1 1/2% some weeks ago. Prices jumped between transactions and bond after bond established a new high for 1921. Volume of bond trading on the New York Exchange rose to \$20,000,000 per day. The reaction from this move has been but slight and the list as a whole has continued to move up in an orderly manner. The average price of 40 representative bonds now stands at \$2.80, or higher than at any time since the fall of 1918. Bond dealers report the market comparatively bare of bonds and the demand unabated. Attractive new issues are being quickly over-subscribed and sell immediately at a premium. The basis of the new offerings shows a decided easing tendency.

Governor Harding of the Federal Reserve Board finds financial conditions growing better, with rapid accumulation of money in banks. He predicts great industrial impetus all over the world if the Armament Conference should result in material reduction of naval and military expenses, as this will reduce taxes and release for other uses large sums now spent on war materials.

Conspicuous in the current bond advance are the old-time railroad issues, many of which are now selling at the highest prices for 1921. While the advance in some cases has already run into two figures, they have not yet recovered half of the ground lost from the 1917 highs, as brought out in the appended table:

	Current price	Advance from 1921 low	Yield, %	1917 high
Atchison, Topeka & Santa Fe 4s, '95	83 1/4	9 1/2	4.85	97
Atlantic Coast Lane 4s, '52	83	9 1/2	5.10	96 1/2

MONEY AND EXCHANGE

Foreign quotations on November 29 are as follows:

Sterling, dollars: Cable	3.99 1/4
Demand	3.99 1/4
Franc, cents: Cable	7.00
Demand	7.02
Lira, cents:	4.12
Mark, cents:	0.43

Eastern Metal Market

New York, November 23.

Activity has developed in the market for tin; a steady business is being done in copper at advancing prices, with the other metals quiet and steady to easy.

Copper grows stronger almost every day. Buying is satisfactory and values have risen.

The Straits tin market has experienced some of the most active days in many months and prices are advancing.

Lead is in quiet demand; prices are steady to firm.

The zinc market is exceedingly dull and values have eased slightly.

Antimony has declined.

IRON AND STEEL

The effort at Washington to link up the steel-rail price with the question of freight-rates for iron and steel may postpone for some time the relief all industry has looked for from lower transportation costs, says 'The Iron Age'. On Tuesday railroad freight executives at a separate meeting in New York decided to continue to March 31 the 28% reduction on iron-ore rates which was to expire December 31. At the same time they declined to grant reductions asked for on coal, coke, limestone, and other raw materials.

The reduction of inventory limits buying by manufacturing consumers of steel, but does not check railroad-car programs which call for 1922 deliveries. At Chicago the 7000 cars let in the past three weeks, the 13,000 now up for bids, and the 8000 for which inquiries will soon come out represent 280,000 tons of steel.

With composite price of seven rolled steel products at 2.1c. per pound, about 88.5% or all but 0.415c. of the projection of the war peak above the ten-year pre-war average has been removed.

COPPER

Strength develops constantly and the market in general is appreciably higher and firmer than a week ago. Buying and inquiry are good from all sources, both foreign and domestic. The electrolytic copper market is strong and active with the major business including first quarter delivery. For this year's delivery the minimum is now 13.50c., delivered, or 13.25c., New York, with nothing less than 13.75c., delivered, for January and first quarter. Sales to England, France, and Germany, particularly the two former, are reported as good at 13.75c. f.a.s. Some producers are not quoting for this year's delivery and some are out of the market even for early next year. Lake copper is quoted at 13.37½ to 13.50c., delivered.

TIN

The most sensational market in Straits tin in many months has been recorded. In fact one large importer characterized the buying of last week, Wednesday to Saturday, as reminiscent of the 'old time' activity. When it is stated that total sales on those days are conservatively estimated to have amounted to close to 2000 tons, its importance can be realized. On Monday and Tuesday of this week the market has been quiet but strong, with spot Straits quoted at 29 62½c., New York. The London market is strong also with spot standard quoted at £161 10s., future standard at £163 5s., and spot Straits at £162. Strength in sterling exchange is also a factor. Arrivals thus far this month have been 2355 tons with 2800 tons reported afloat.

LEAD

The market is without feature but continues to be characterized by a steady quiet demand at firm prices. In fact consumption and production seem to be pretty evenly balanced. The quotation of the American Smelting & Refining

Co. is unchanged at 4.70c., New York and St. Louis, while in the outside market there are sellers at 4.70 to 4.75c., New York, or 4.35c., St. Louis, all for early or 30-day delivery. Reports from England indicate a scarcity of the metal there and higher prices.

ZINC

The market for prime Western is exceedingly quiet and slightly easier. Galvanizers and other consumers have apparently bought to cover their immediate needs and perhaps those for this year. At any rate business is small and as a consequence values are easier, there being one or two sellers willing to take the business offered. Prime Western for this year's delivery is quoted at 4.65 to 4.70c., St. Louis, or 5.15 to 5.20c., New York, but the amount available is not large. Most producers are either well sold into November or are holding back in the confidence that higher prices are in store.

ANTIMONY

Wholesale lots for early delivery are now obtainable at lower than recent prices being quoted at 4.50c., New York, duty paid, for wholesale lots for December delivery, with prompt at 4.55c. and jobbing lots at about ½c. higher.

ALUMINUM

Virgin metal, 98 to 99% pure, continues to be quoted by the leading interest at 24.50c., f.o.b. plant, in wholesale lots for early delivery, but it is believed that importers' prices for the same grade at 17 to 18c., New York, duty paid, are being met by the producer referred to. Demand, however, is not heavy.

ORES

Tungsten: There is nothing fresh to report. The market is still inactive and prices are nominal at \$2.50 per unit upward, depending on the quality, tonnage, and delivery.

Molybdenum: There is no activity and nominal quotations prevail at 45 to 50c. per pound of MoS₂ in regular concentrates.

Manganese: Absolute lack of demand characterizes this market and quotations are nominal at 20c. per unit, Atlantic ports, for high-grade foreign ore. Imports in October were heavy at 36,760 gross tons, being the total for the 10 months of the year to 377,834 tons against 467,772 tons to November 1, 1920.

Chrome: No change in conditions is ascertainable. Quotations continue nominal at \$20 to \$26 per net ton, c.i.f. Atlantic seaboard, for foreign ores of standard quality.

FERRO-ALLOYS

Ferro-manganese: Sales of small lots of British and domestic alloy are reported at a basis of \$58.35, seaboard, but demand is generally very light. Imports for October were 1943 gross tons, which make the total to November 1 only 8548 tons as compared with 46,739 tons on November 1, 1920. Exports in October were only 10 tons or 318 tons to November 1, this year, and 2170 tons to November 1, 1920.

Spiegeleisen: Demand is confined to small lots for early delivery at the prevailing quotations of \$25 to \$26 per ton, furnace, for the higher grade.

Ferro-tungsten: In an inactive market quotations continue nominal at 40 to 45c. per pound of contained tungsten in the domestic alloy and at 50c., duty paid, seaboard, for the foreign.

Ferro-silicon: The 50% alloy is quiet and steady at \$60 per ton, delivered, the cheaper lots having been absorbed, it is believed. Sales are confined to a few small lots.

Ferro-chromium: Demand is insignificant at prevailing quotations of 10 to 14c. per pound of contained chromium, delivered, in standard 4 to 6 or 6 to 8% carbon alloy.

Current Prices of Commodities

The figures given on this page represent the regular current price, at the time of our going to press, to industrial buyers of standard commodities in small wholesale lots on San Francisco Bay. They should not be construed as being quotations nor as being either the lowest or the highest price; they are given rather as a guide by which to follow the trend of the market or to estimate the approximate cost of materials and supplies.

ELECTRICAL SUPPLIES

Armored copper cable, size 8, BXL 3, lead and armor, 100-ft. lots per 1000 ft.	700.00
Armored copper cable, size 8, BX 3, armor, 100-ft. lots, per 1000 ft.	375.00
Conduit, galvanized iron, 3/4-in., per 100 ft.	10.65
" " " " " 2-in. " " "	33.45
Copper wire, size 0, bare, 200 to 1000-lb. lots, per 100 lb.	18.70
" " " " " 10, triple-braid, weather-proof, coil lots, per 100 lb.	21.50
" " " " " 14, single-braid, rubber-covered " per 1000 ft.	7.35
Insulators, glass for telephone, No. 0 pony, per 1000.	86.50
" " " " " power, No. 14, per 1000.	103.00
" " " " " porcelain, 6000 v., No. 41, per 100.	19.30
Porcelain knobs, No. 5 1/2, 10d. 'nailit', per 1000.	20.40
" " " " " " " solid, per 1000.	20.20
" " " " " 3 1/2 " " "	69.20
" " " " " tubes, 5/16 by 3-in. " " "	0.95
" " " " " " " 6-in. " " "	38.15
Sockets, weather-proof, molded, No. 00, 66d, per 100.	27.60
Telephone wire, iron, size 12, half-mile lots, per 100 lb.	8.75

EXPLOSIVES

Blasting-caps, No. 6, in lots of 5000, per 1000.	17.00
" " " " " electric, 6-ft., No. 6, in lots of 1000, per box of 100.	8.73
Blasting-powder, "B" soda, in 100-keg lots, per keg of 25 lb.	2.10
Dynamite, nitro-glycerine, 40%, in ten lots, per 100 lb.	19.00
" " " " " gelatine " " "	19.00
" " " " " ammonia " " "	18.00
Fuse, common, in case lots, per 1000 ft.	7.22
" " " " " waterproof, triple tape, in case lots, per 1000 ft.	9.01

FUELS

Coal, Utah steam, \$3.50 at mine, plus \$7.50 freight to California terminal points, in carload lots, per ton.	11.00
Coal, black-mith's, in carload lots, per ton.	21.00
" " " " " in small lots, per ton.	24.00
Coke, in carload lots, per ton.	25.00
Fuel oil, per barrel.	1.50
Diesel oil, per gallon.	0.06
Distillate " " "	0.16 1/2
Gasoline " " "	0.22 1/2

HARDWARE

Anti-friction metal, per pound.	0.16
Babbitt, genuine " "	0.42 1/2
Brass sheets, half-hard and soft, per pound.	0.24 1/2
Drill-steell, hollow, first grade, in ton lots, per pound.	0.18
" " " " " solid " " "	0.11
Fish-plate bolts, 3/8 by 2-in., per 100 lb.	8.15

Nails and spikes (20d to 60d base), per keg.	4.90
Nails, hot pressed, 3/4 in., hexagonal, per 100 lb.	9.45
" " " " " cold punched " " "	11.25
Picks mining, 5-lb., per dozen.	12.00
Shovels, carbon steel, No. 2, long handles, per dozen.	15.00
Track spikes, 3/4 by 4 in., per 100 lb.	1.00

HEAVY STEEL AND PIPE

Bar steel, roft, per 100 lb.	3.75
Rails, steel, 16-lb., per 100 lb.	3.80
Reinforcing-steel, per 100 lb.	3.75
Sheets, corrugated, galvanized iron, 20 gauge, per 100 lb.	6.55
" " " " " flat " " "	6.45
" " " " " flat, black iron " " "	5.90
Structural T's, channels, angles, and beams " " "	3.85
A deduction of 15c. per 100 lb. is made on the above when purchased in carload lots.	
Bars, steel, square, cold rolled, per 100 lb.	6.50
Pipe, wrought-iron, black, standard, 1 1/2 in., per 100 ft.	12.40
" " " " " galvanized " " "	15.70
" " " " " black " " " 4 in. " " "	52.45
" " " " " " " extra strong " " "	95.25
Shaffing, cold-rolled (2 1/4 to 3 in base) " " "	5.25

HOBSTING-ROPE

Discounts for delivery from Pacific Coast stocks are: cast-steel, 22 1/2%; extra strong cast-steel, 30%; plow-steel, 35%; blue-steel, 20%. The following illustrations indicate the net price for each kind of rope, in standard, 6-strand, 19-wire, 1-in. rope.

Blue-centre rope, per foot.	0.40
Cast-steel rope, per foot.	0.24
" " " " " extra strong, per foot.	0.24
Plow-steel rope, per foot.	0.28

LUMBER

The figures given are subject to variation, depending upon the size and length. A charge for cartage is also to be added. Prices are furnished by Van Arsdale, Harris Co.

Fir, No. 2 clear and better, 1 to 2 in. thick, up to 16 in. wide, per thousand feet (M)	75.00
" " " " " common, base price, per M.	28.00
Fir, common, 6 by 6-in. up to 12 by 12-in., per M.	34.00
Redwood, rough merchantable, 1 to 4 in. thick, per M.	45.00 and 50.00
" " " " " clear, 1 to 2 in. thick, up to 12 in. wide, per M.	90.00
Spruce, 'B' and better, 1 to 2 in. thick, up to 16 in. wide, per M.	80.00
Sugar-pine, No. 1 and 2 clear, 2 in. thick, up to 16 in. wide, per M.	200.00
White pine " " "	150.00

MISCELLANEOUS

Air-hose, 1-in., 5-ply, plain, per foot.	0.48 to 0.65
Candles, 'Granite' mining, 0-16-40, 10-case lots, per case.	6.40
Carbide, in 100-lb cans, per can.	7.75
Cotton waste, best grade, per 100 lb.	11.50
Diamonds for drilling, according to size, per carat.	50.00 to 75.00
Manila rope, grade 1, per pound.	0.17
" " " " " 2 (standard), per pound.	0.14
Packing, flax, per pound.	0.33 to 0.85
" " " " " sheet " " "	0.25 to 1.00
" " " " " steam or water, first grade, per pound.	0.90
Silex lining, crated, per long ton.	41.00
Tube-mill pebbles, Danish, selected (in bags), per long ton.	32.00
Zinc-dust, in 250-lb. boxes, per 100 lb.	9.00
" " " " " sheet, 36 in. by 84 in., No. 0 gauge, in tons lots, per 100 lb.	13.50

PORTLAND CEMENT, LIME, ETC.

Fire-brick, clay, per 1000, in carload lots, Livermore Star Brand.	55.75
Fire-clay, in bags, per ton.	18.00
Lime, lump, in barrels, per barrel of 180 lb.	2.65
Portland cement, in bags, per barrel of 380 lb.	3.95
Allowance of 15c. for bags returned in good condition	
Portland cement, in barrels, per barrel of 400 lb.	4.55
A deduction of 50c. per barrel is made on lime and cement when sold in carload lots.	

ORES AND MINERALS

The following prices represent approximately what can be obtained for the products indicated delivered at points on San Francisco Bay. The price, of course, vary widely with the grade and purity of the ores. The present stagnant condition of the market makes many of the quotations purely nominal; most of the ores can be purchased at these prices, but it should be understood that it is not easy for the producer to market them at this time.

Antimony ore, approximately free of lead and arsenic, not less than 50% Sb, per %.	60c.
Asbestos (crysotile), according to length of fibre, per ton.	\$20 to \$2500
Barite white and free of iron (crude), per ton.	5 to 10
Bismuth ore not less than 20% Bi, per % Bi.	10 to 15
Feldspar, crude, lump, free of iron, per ton.	5 to 10
Fluorspar 85% calcium fluoride, per ton.	15 to 20
Fuller's earth ground to pass 80-mesh, per ton.	5 to 10
Graphite, crystalline, per pound.	3c. to 6c.
Magnetite, calcined, per ton.	25 to 35
Manganese ore, less than 0.75% Fe; less than 6% SiO ₂ , per ton.	25 to 30
Mica, according to size, clearness, and cleavage, per pound.	1 to 8
Molybdenite not less than 85% free of copper, per % MoS ₂ .	8 to 12
Ochre, according to strength, crude, per ton.	8 to 15
Sulphur, 99.5% pure, only trace of As and Se, per ton.	15 to 18
Talc, lump, white, per ton.	7.50 to 10
Tin ore, not less than 60% Sn, per % Sn.	4 to 6
Tungsten ore, not less than 65% WO ₃ , per % WO ₃ .	2.75 to 3.00

Company Reports

BROKEN HILL PROPRIETARY CO., LTD.

Report for the year ended May 31, 1921.

Property: Mines, mills, plants, and steel works in Australia.

Operating Official: Essington Lewis, general manager.

Financial: Gross profits, £513,087 1s. 6d.; depreciation deduction, £161,755 12s. 3d.; net profit, £351,331 9s. 3d.

Production: Upon the cessation of the strike at Broken Hill on November 10 last, work was resumed as expeditiously as possible and continued for about two months, when it was found that operations could not be continued except at a serious loss, due to the increase in cost of labor and reduced working hours. Operations were suspended in January and have not been resumed. This serious position was accentuated by the disastrous fire that took place at the roasting plant at Port Pirie in January. The mine produced 3875 tons of ore during the period under review; the concentrating mill treated 4420 tons, producing 801 tons of lead concentrate. The re-grinding section of this plant treated 17,028 tons of tailing, producing 557 tons of lead concentrate and 2007 tons of slime. The slime-flotation plant treated 16,558 tons of slime, producing 1487 tons of lead concentrate, and 4257 tons of zinc concentrate. The production from the Newcastle steel works operated by the company was as follows: Pig-iron, 227,533 tons; steel ingots, 209,458 tons; coke, 240,905 tons; sulphate of ammonia, 3355 tons; and tar, 2,456,960 gallons.

NORTH BROKEN HILL, LIMITED

Report for the year ended June 30, 1921.

Property: Mines and mill at Broken Hill, New South Wales, Australia.

Operating Official: G. Weir, general manager.

Financial: Mine production, interest, rents, and dividends, £183,492 9s. 7d.; mine expenditure, £147,892 2s. 1d.; balance to appropriation account, £8128 15s. 6d.;

Development: The quantity of ore available for stoping above the 1400-ft. level remains unaltered and is estimated at 2,600,000 tons.

Production: Milling operations were resumed on February 7, and from that date till June 30, 32,300 tons of ore was treated producing 6461 tons of lead concentrate, assaying 65.5% lead, 28.4 oz. silver, and 7.3% zinc; and 6010 tons of zinc concentrate, assaying 48.1% zinc, 7.6% lead, and 9.6 oz. silver per ton.

General: The construction of the new flotation plant having been completed, the ore raised from the mine is now wholly treated at the company's mill and with excellent results, producing high-grade lead and zinc concentrates.

CITY DEEP, LIMITED

Report for the quarter ended September 30, 1921.

Financial: Working revenue, £598,885; total profit, £210,994.

Development: 6885 feet.

Production: 263,900 tons crushed for a yield of £2 5s. 7d. per ton.

Remarks: The profit for the quarter constitutes a record for the company.

BROKEN HILL SOUTH, LIMITED

Report for the year ended June 30, 1921.

Property: Mine and plant in New South Wales, Australia.

Operating Official: W. E. Walnwright, general manager.

Financial: Ore extraction, treatment, mine development, and cessation expenses, £180,556 14s. 6d.; mine production and realization from previous periods, £131,727 14s. 7d.; loss, to appropriation account, £56,701 17s. 11d.

Development: 557 ft.; ore-reserves, 3,500,000 tons.

Production: mined, 37,007 tons assaying 14.4% lead, 8.7 oz. silver per ton, and 15% zinc; lead concentrates produced, 14,307 tons, containing 7801 tons lead, 510,560 oz. silver, and 1730 tons zinc.

General: A large portion of the report is taken up with the details of the various industrial disputes that occurred during the year.

CHIEF CONSOLIDATED MINING CO.

Report for the quarter ended September 30, 1921.

Financial: Receipts from shipments of ore, after deducting smelting, transportation, and sampling charges, \$489,534.45; net profit after payment of all charges, \$72,939.66; dividend paid August 1, \$44,201.10, November 1, \$44,201.10.

Development: Chief Consolidated mine, 10,654 ft.; Plutus mining company, 160 ft.; total of all development work, 10,814 feet.

Production: Tons, silver-lead ore, 9882; dry ores, 12,234; metal contents, 1142.153 oz. gold, 735,922.93 oz. silver, 3,270,749 lb. lead, and 3082 lb. copper.

Remarks: During the period of July 15 to August 15, the former world's record of 310 ft. was broken by a progress of 427.5 ft. in the Water Lily shaft.

AMERICAN TRONA CORPORATION

Report for the year ended December 31, 1920.

Financial: Expenses, \$2,084,939.93; sales, \$1,449,109.73; other income, \$166,789.35; net loss carried to balance sheet, \$267,794.02.

Production: 10,100 tons of potash salts and 4400 tons of refined borax.

General: The plant at Searles Lake continued operations until the end of April of this year, when it was deemed advisable to suspend, pending an improvement in market and general conditions. A small organization composed of experienced technical men are continuing research.

MODDERFONTEIN DEEP LEVELS, LIMITED

Report for the quarter ended September 30, 1921.

Financial: Working revenue, £397,254; total profit, £265,263.

Development: 2196 feet.

Production: 129,900 tons crushed for a yield of £3 1s. 2d. per ton.

T. A. RICKARD. . . . Editor

THE burial of the unknown soldier at Arlington, and the various legislative enactments intended to assist those who served in the Army, express the sentiment of gratitude to those who fought and died in the War. There is one thing that could be done, particularly in San Francisco, to help disabled soldiers, and that is to give them the job of selling cigars. Every visitor to our city notices the large number of cigar-stands that occupy our street-corners; these are tended by vigorous men who might well be engaged in something productive and who could be replaced advantageously by crippled soldiers. The retail trade in cigars needs no salesmanship; the buyer knows what he wants and simply asks for it. Why not give the job to our soldier boys? Any cigar-store that set the example would win popularity at once.

WHAT proportion of the gross output of a gold mine is profit? The question is prompted by the answer, which we see before us in the form of the statistical record of three Rand mines as quoted in a recent issue of the 'South African Mining and Engineering Journal'. The three mines are the New Heriot, Village Main Reef, and Wemmer, all of which are now exhausted and dead. These are the figures.

	Tons milled	Total output	Dividends declared	Dividends per ton
Heriot	3,000,317	£5,575,745	£1,483,277	9.89s.
Village	7,005,952	12,249,101	4,080,143	11.65
Wemmer	1,038,364	2,647,327	839,180	16.16

Thus the dividends represent about a third of the value of the gold produced. This, we venture to say, is a high proportion. Here are a few others. The Bunker Hill & Sullivan, which is still very much alive, has paid 26% of its gross production in the shape of dividends; the Goldfield Consolidated paid 58%; the Alaska-Treadwell, 40%; the Camp Bird, 70%; the Mysore, 47%; the Mount Morgan, 40%; the Esperanza, 33%; the Robinson, 54%; and the Homestake, 25%.

A premium on gold as measured in paper currency is a pleasant thing for the miner in South Africa, but it introduces a factor so variable as to keep him in a nervous state. The rise and fall of the premium corresponds with the fluctuation in the value of the paper pound as measured in American dollars, so that the rate

of exchange at New York is the barometer of industrial felicity at Johannesburg. When, for example, the paper price of gold drops from 115½ shillings per ounce, as it was in August, to 104 shillings, as it was in November, the operators on the Rand tremble for the solvency of their low-grade mines. Indeed, recently they felt such painful quahms that they went to General Smuts, the Premier of the South African Union, and begged him to do something for them. The General received the deputation courteously and reviewed the position in terms that met with their approval. He pointed to the fact that, out of the 39 active mines, 24 would have to be closed down if the so-called premium disappeared. Even a steady price of under 100 shillings per ounce would extinguish the profitable productivity of half a dozen mines. He said: "If, for instance, America cancelled the war debt owing by Great Britain to the United States, the exchange between Great Britain and America would be restored and the gold premium would disappear in one swoop". This illustrates forcibly how one man's food is another man's poison. However, it is considered unlikely that the British war debt will be cancelled, and it is even doubted if the cancellation would restore the exchange to normal, so our friends on the Rand may take another breath without feeling the pains of a financial plenury. One might say that the restoration of the pound to parity would be compensated by its greater purchasing power in terms of mining machinery and supplies, but unfortunately these economic readjustments do not take place simultaneously, as we know only too well from our own experience in this country. Therefore the South African Premier falls back on the one alternative—increase of efficiency. One suggestion is to allow the native to perform more of the work that is done by the higher-paid white employee. The miners' delegates protested, of course, against this proposed lifting of the 'color bar' and threatened a strike. To which the operators replied that they could either be reasonable or join the ranks of the already numerous unemployed.

TO the above we are able to add later news. General Smuts has scored again. It is estimated that his successful intervention in Rand affairs is equivalent to a gain of "at least 40%" in the efficiency of native labor at the mines. Hitherto the Kaffirs have been restricted to a 5-hour shift as against the standard 8-hour working day

for white laborers. This regulation, and the further limitations on the kind of work the native might do, has been a severe check to economy in the operation of the mines in and around Johannesburg. The new arrangement represents a concession on the part of organized white labor on the Rand and indicates that the unions realize the need, for themselves, of decreasing the operating cost so that sundry low-grade mines may continue to be operated profitably. The event is of paramount importance to mining in South Africa, and it gives us great pleasure to record it. At the same time it is announced that an agreement has been reached between the Custodian of Ex-Enemy Property in South Africa and the Public Trustee in England for the allocation of ex-enemy shares among the mining companies and financial houses, whereby some \$30,000,000 worth of stocks will be absorbed, and thus cease to be a menace to the market.

UNDER 'Discussion' we publish a letter from Mr. H. M. Merry, of Salt Lake City, describing a graphic method for comparing three variables; he illustrates the application of his method to the solution of a problem in the leaching of copper ore. We understand that this isometric chart was first used by Mr. Merry when he was chief statistician, and, later, chief engineer for the Chino Copper Company, at Hurley, New Mexico. It proved a satisfactory device. Our old friend, Mr. H. W. Reed, also a resident of Salt Lake City, suggests that the metric system could be popularized by using English names for the units. Mr. Horace G. Nichols writes from Vancouver on the subject of the mining geologist, apropos of Mr. Augustus Loek's article in 'Economic Geology'. Mr. Frank Hall, of Tonopah, makes a plea for the prospector, and explains why he has disappeared. He attributes the result in part to the decay of the grubstake system and in part to the unfair treatment to which prospectors are subjected by engineers. We do not agree with Mr. Hall in the last of these conclusions, but we are glad to give space to a frank statement from one side, hoping that some representative engineer will join us in assuring the prospector that he is mistaken in assuming, as is done so often, that the engineer is as much his natural enemy as a fox to a fowl. We agree that one of the essentials to the discovery of ore is digging. The hotel-stove gossips or the plaza miners are not the fellows to find ore. More work, and less conversation, is needed for the purpose. A prospecting venture ought to be started locally, for it is on the small syndicate or the party of working miners aided by local tradesmen that genuine prospecting must depend, despite the large-scale and more scientific methods of big corporations. As for direct Government aid to prospecting, we have not come to that yet. The Government does assist by its scientific investigations and publications, and by giving special information to those who ask for it. If the prospector does not derive much benefit from such sources of knowledge, it is his fault, for the information can be obtained by anyone taking the trouble to ask for it. Some of it is couched in terms not understandable by those lacking a

technical education, and it may be that the reports of the Geological Survey and of other Federal bureaus could be given a wider scope if written in simpler English. That is a suggestion that we have made more than once.

RETICENCE on the part of the officials of copper-mining companies as to the date on which operations will be resumed is natural for a number of reasons, one of which probably is a disinclination to encourage their old employees by premature announcements that might lead to disappointment. One of the first large companies to resume will doubtless be Utah Copper; unquestionably it could make a profit at the present price of the metal, but the company's large output would postpone the further reduction of the existing surplus to reasonable size. Accordingly, the policy of the company to defer resumption seems prudent. However, Mr. R. C. Gemmell, the company's general manager, has vouchsafed a "conjecture"—as the press-reports have it—that the date of resumption will be April 1, although he declares he cannot set any certain date. The estimated consumption of copper during November was 200,000,000 pounds, whereas the current production in this country and South America is only about 40,000,000 pounds per month. Considering the rapidity with which the surplus is being absorbed we risk the prediction that the idle employees of the Utah Copper Company can make their plans on the probability of returning to work not later than April 1—perhaps sooner. And in this respect the employees of several other copper companies may take a similarly optimistic view. The mines that produce the metal at a relatively high cost—say, 15 cents per pound—will have to wait awhile before they re-awaken to profitable activity. It is unlikely that the copper companies will act in unison in this matter of resumption of production, because their economic circumstances differ widely, and there seems no reason why the low-cost producers should wait until the market price of copper is high enough to ensure a profit to the high-cost producers. It is an example of the law of evolution: the survival of the fit, that is, those fitted to be successful under competitive conditions.

Royston, or San Antone

In these days of reviving cheerfulness in mining affairs it is pleasant to read of new finds that bear the promise of expanding activity. The old San Antone district in southern Nevada is attracting attention on account of the discovery of rich silver ore on a claim located long ago. The locality has been named Royston; the story has been published in a fragmental way at intervals in our news department during recent weeks. It appears that in October a miner named Frank Betts leased a strip of ground only 500 feet square from the Hudson Mining & Milling Company. With his partner, Cunningham, he started to work. They needed water and a means of haulage for supplies, their camp being 28 miles north-west of the nearest distributing point, which

is Tonopah; so they gave a quarter interest to the water-carrier, George Box, in exchange for his services. Another partner came in the person of a Chinaman, Charlie Poy, a dealer in poultry at Tonopah, who, like others of his race living in our Western mining communities, is alive to the spirit of mining adventure. Betts and Cunningham needed money for their prospecting, so one of them approached Poy, who went himself to see the ground and to judge of its promise as a mine. He bought a quarter interest for \$150, and, it is sad to relate, was arrested for drug-selling soon after his return to Tonopah! He is now in jail. Meanwhile his partners went to work and almost at once uncovered a vein four feet wide of silver ore that assayed 'in the hundreds' of ounces per ton. Within six weeks, from a hole only 24 feet deep, they shipped \$20,000 worth of ore. Ten tons sent to the McNamara mill realized \$7150. So far the prospect has no dump, for all the rock has proved to be rich ore. Naturally there has been a rush to the locality and the Hudson company has granted a number of leases. This company is controlled by the Walker family of Salt Lake City and Mr. W. H. Royston, after whom the district has been re-named. Mr. Royston is superintendent of the Tonopah-Behmont Development Company's mill at Tonopah. Another fortunate owner of ground near the discovery is the Super-Six company, which with the Hudson company has joined in granting over 30 leases to parties of prospectors. The desert is dotted now with tents, and automobiles come purring from every direction. It is a 'boom', such as is most welcome at this time. Several of the companies operating at Divide and fortunate enough to have money in their treasuries have taken leases at Royston, so that systematic exploration on a considerable scale is assured. This part of Nevada is traversed by two nearly parallel ranges of mountains, the Toyabe and Shoshone. On the west side of the latter are the old mining centres of Lodi, Grantville, and Downeyville—not to be confused with the mining town of Downieville in California. Across the intermountain valley is Ophir canyon, where Mr. Louis Hanchett senior did some mining as early as 1876. This old camp is 15 miles north of San Antonio, or Royston, which is in the southern part of the Toyabe range. At its extreme northern end is Austin. So, it will be noted, the surrounding region has been the scene of several mining excitements and of a good deal of desultory prospecting, but much of it has been explored only superficially and now invites closer examination. The story of the new find at Royston reminds one of the manner in which the rich silver orebody at Randsburg, California, was discovered, as related by Mr. A. B. Parsons in our issue of November 12. Such finds bring home the fact that mineral exploration is fortuitous and anything but scientific in its character. Much of the exploratory work done in our old mining districts was not guided either by knowledge or experience sufficient for the purpose, so that rich orebodies were missed, to be found almost by accident in these later days. Indeed, one may say that if a radio-active vision were vouch-

safed to anyone, so that he could see through rock as a surgeon sees through human tissue to the vital organs, it would surprise him, and the rest of us, to discover how ineffective had been the search for ore on the part of the prospector and engineer, and how many rich orebodies had been missed.

Freight-Rates and Mining

High freight-rates imposed by the railroads are strangling the mining industry of Nevada, according to the conclusions reached at a conference held last week at Carson City, in which participated representatives of the Nevada Mine Operators Association, the State Railroad Commission, the smelting interests, and of the railroad companies themselves. No inclination was manifested to condemn the railroads out of hand; rather, the purpose was to place the facts before the railroad officials with a view to demonstrating that "co-operation"—which in plain English means reduction of rates—on the part of the railroad companies is required to revive the mining industry, and that the railroads will suffer less financially from the lowering of freight-rates than from the loss of traffic attendant upon inactivity of the industry. The mine operators showed that, notwithstanding the lessened cost of labor, as well as of lumber and sundry other commodities, and notwithstanding the fixed market price for the metal in their ores, numerous gold and silver mines had been forced to suspend production on account of the high cost of transportation and high treatment-charges imposed by the smelting companies operating in Utah, where most of the high-grade Nevadan ores are treated. Representatives of the smelters thereupon submitted evidence to show that excessive freight-rates applying to fuel, limestone, and essential fluxing ores make it impossible for them to reduce the prevailing schedules of settlement for ores that they purchase. With the responsibility thus apparently thrown upon them, the railroad officials merely advanced the stock argument of high operating cost and assured the conferees that they were as anxious as anyone to stimulate the industry, and that rates would be lowered just as soon as such action could be taken consistently. It is unreasonable to place all the blame on the railroads, for there are too many other factors; nevertheless the proceedings at Carson City are significant for the reason that the condition of the mining industry in Nevada is typical of that in every other Western State; indeed, every industry throughout the country is suffering under handicaps arising from high freight-rates. One of the principles on which is based the system of making freight-rates, is that the rate shall be low enough to 'move the traffic' so long as it does not involve an actual direct operating loss. This principle depends upon two simple but sound theories: (a) that more traffic permits a thinner distribution of overhead and fixed charges, and (b) that traffic begets traffic. If, for example, the silver mines at Eureka, Nevada, were producing ore today, instead of lying almost idle, materials, machinery, and supplies of all kinds would be flowing into Eureka, and

the railroads would be earning a net profit even if the revenue derived from freight on ore only equalled the direct cost of the actual hauling. The railroad officials know to a cent just how low they can afford to fix rates to the end that the mines and smelters may operate profitably; it is possible, but unlikely, that this point has been reached in the establishment of a great many rates. We venture to say, however, that, if the railroads were independent agents, as they were twenty-five years ago, there would be an immediate downward adjustment that would put many an industry on its feet. Now, with the Federal Labor Board determining the wages of railroad employees on the one hand, and the various State and Interstate commissions fixing rates on the other, the railroad executives naturally are circumspect and cautious in voluntarily reducing rates below the maximum prescribed by the commissions. This does not necessarily imply an opinion that the railroads are subjected to too much regulation; but it does point to the fact that close governmental regulation is not an unmixed blessing. It seems altogether probable that many of the existing rates in Nevada can be lowered to the mutual benefit of all concerned. Reductions of one kind and another are being announced daily; specific instances of lessened rates on ore and concentrate in Idaho, Montana, Utah, and Arizona have been recorded in our news columns during the last two months. The institution of proceedings, the holding of hearings, and the final obtaining of a decision from the Interstate Commerce Commission would have consumed the greater part of two years; the mine operators of Nevada desired immediate action. They displayed excellent judgment in arranging the recent conference and in stating their case candidly to the railroad officials. Relief should be forthcoming.

A Detachable Rock-Drill Bit

The fundamental operation of mining is the breaking of virgin rock. The force is supplied by dynamite, but to make the strength of the dynamite in any degree effective it must be detonated in a long slender hole; therefore, the making of this hole is the primary act of mining. Forty years ago the first air-driven rock-drilling machines were manufactured, and since that time they have been gradually improved until, in the light of present knowledge, they seem to be efficient, although it would be rash to prophesy that the present type of drill will not be obsolete by the end of the next decade. The machine, however, is only a source of power; the instrument that actually eats into the rock is the piece of steel that receives the 1800 blows delivered each minute by the hammer, and is rotated by the machine. As someone has remarked, the "whole mining operation is pyramided upon the drill"; indeed, he might have gone further and said that it is based upon the drill-bit. If the constant grinding against solid rock did not wear out the bit, the mine superintendent would be spared one of his troubles. The intelligent observer would ask, "Why not make the drill of better steel?"; the answer is, the cost would be prohibitive. The question then

arises, why not weld to the drill a short piece of high-grade steel and use this for the bit? and when the impracticability of this is explained a really perspicuous observer would ask, "Why not make a detachable bit? ". That is exactly what inventors have been trying to do for twenty years. In the Patent-Office at Washington repose dozens of designs of detachable bits that look exceedingly well on paper. Some depend on springs, others on pins or wedges or keys or sleeves or threads to make the union, but none of them has been able to stand the hard work in a mine. The advantages of a successful detachable bit so small that a machine-man can carry half a dozen in his pocket are well known, but the more important of them are worth enumerating: (a) it will avoid a vast amount of unnecessary work in collecting dull drills from the stopes and drifts, carrying them to the station, hoisting them to the surface, and delivering them to the shop—a succession that must be reversed when the sharpened drills are returned to the mine; (b) it will save the wages of blacksmiths and helpers, the first cost of elaborate drill-sharpening shops and machinery, besides the fuel and compressed air used; (c) it will diminish measurably the amount of steel needed, as represented in short drills that are thrown away, dull ones that are thrown into the fill by irate drillers, and the metal that is burned each time a drill is sharpened; (d) it will increase the efficiency of the actual drilling operation because the greater durability of alloy-steels will promote efficient cutting while the drill is in the hole; (e) it will obviate waiting at the face for sharp steel, or, on the other hand, the necessity for continuing to use the old pieces when they are too dull for efficient work; (f) it will reduce the amount of compressed air consumed per foot of hole drilled. According to the 'Anaconda Standard', such a device has now been perfected by Mr. Arthur L. Hawkesworth, a mechanic in the employ of the Anaconda Copper company. A brief description says that the novelty consists of a special double taper by which a bit of vanadium-steel, weighing only a few ounces, is securely fastened to the end of a piece of ordinary drill-steel. It is claimed that the bit will 'stand up' under severe service, that it will not jam in the hole, that it consists of a single piece with no delicate parts to wear or break, and that it can be loosened for removal by one tap on the right spot with a hammer. This sounds almost too good to be true, but it is said that repeated tests have been made in the mines at Butte and that some of the officials of the Anaconda company are convinced that the bit will be a success. It might be supposed that the manufacturers of drill-sharpening machines and the makers of drill-steel, who may lose some business at the outset, will not look with favor on such an innovation; but we feel safe in assuring the doubtful ones that the manufacturers are much too far-sighted to frown upon any invention that will help so much to promote the prosperity of the mining industry. If Mr. Hawkesworth's device proves to be only a flash in the pan, it is to be hoped that someone else may invent a workable bit.

DISCUSSION

Graphic Analysis of Three Variables

The Editor:

Sir—In the course of exhaustive researches into the many phases of metallurgical practice now commonly conducted by all mining companies, the investigator is called upon not only to satisfy himself of the truths apparently revealed by his work but to convince the operating staff of the value of the evidence obtained. The latter is not always easily accomplished, so it may not be amiss to present a graphic device that performs a definite service for the engineer so engaged, both for his own clearer conception and for the visual enlightenment of his principals.

The accompanying chart-form possesses the useful quality of comparing three variable factors simultaneously and in a strikingly unmistakable manner. To illustrate the method, comparison is made between the influence of acid-leachable copper and of finely-ground feed upon the recovery of copper from a flotation process. Although the data used are imaginary, a similar condition from mill practice, showing characteristics fully as marked, is within my recent experience. The scheme was utilized in an effort to analyze the same problem, and a long-standing argument between two schools of opinion was settled so effectively thereby that it seems worth describing for the use of others.

Ordinary isometric-ruled paper is used. Scales are chosen within the limits of the data for the two base ordinates, X and Y , which should represent the influences to be weighed; the vertical, or Z ordinate, should indicate the recovery, or the result upon which the influences are supposed to act. From the intersection of the plotted X - Y ordinates, the vertical Z ordinate is erected on a convenient scale. When all data are plotted, if marked characteristics are observed, typical curves should be superimposed; these will represent the average course of the influence lines and thus illustrate the condition. When dealing with a phase into which more than three factors enter, each factor should be plotted alternately

with all others, to avoid the chance of reaching a wrong conclusion.

In the example it is clearly apparent that the degree of recovery is directly proportional to the amount of material passing 200-mesh in the feed, and that the assay percentage of acid-leachable copper is of slight influence. Points along the X -axis, both maximum and minimum, show almost no variation in relative magnitude, whereas on the Y -axis a pronounced increase in recovery follows finer grinding of the feed.

ISOMETRIC CHART FOR COMPARING THREE VARIABLES

Judiciously employed, this scheme should be useful in analyzing, for example, the influence of the various and often deleterious salts present in the leaching solutions of hydro-metallurgical processes, or in any study in which the effect of two or more influences upon a result is to be ascertained; it is possible to visualize relationships and tendencies that are not comparable by other methods.

I do not claim originality for the chart-form, which is well known to electrical engineers and mathematicians, among others; but its application to practical metallurgical or engineering investigation is believed to be novel and worth while.

Metric Weights and Measures

The Editor:

Sir—I believe that one reason why we have made so little progress toward adopting the metric system is be-

cause the names mean nothing to ninety-nine million of our people. If Congress would by law make the yardstick equal in length to the French metre and call it a metric yard, and then divide it decimally, its adoption would present no difficulty and invite little objection. In the same way we could have a metric quart. We already have a metric ton, why not have a metric mile? I make the suggestion and leave it to your readers to see how easy the details can be worked out without taking up valuable space in your journal.

Salt Lake City, November 11,

H. W. REED.

Why the Prospector has Disappeared

The Editor:

Sir—In your issue of April 23 appeared an interesting and instructive article on prospecting. I ask you to publish a prospector's view of the subject.

In pioneer days when every stream was alive with fish and when there was an abundance of game, all that the prospector required was a little bacon and flour. There was plenty of feed for his burros or pack-animals, but this has since been appropriated by the cattle-man or has been destroyed by sheep. The country was virgin and unexplored. Every day held forth a promise that rich ore might be found. Mines and croppings stuck up out of the ground. In one prospect in Nevada, which afterward became a famous silver-lead mine, \$80,000 worth of ore was exposed in the outcrop at surface. When the early prospector was short of grub, the old-time manager gave him a job; not infrequently he returned to offer a prospect that later became the property of his employer; or he could easily obtain a grubstake, a good investment when the country was new, for a mine might be found on a small investment. The grubstake is the foundation of many an American fortune. The expert was not so much in evidence in those days.

The engineer never knew how to deal with the old-time prospector, many of whom owned good properties but had no conception of the value of money; they would speak of \$100,000 or \$1,000,000 as if it were a trifle. During the early history of Virginia City, Nevada, a company that had developed a mine desired to purchase the adjoining ground. The manager met the prospector on the street and told him to be at the bank at 10 o'clock the next day, when he would receive \$60,000 in cash for his holdings. At the appointed time he was there with a sack to receive the money. The bank teller paid in \$20 gold pieces, counting it out in \$1000 piles. By the time \$30,000 was in sight the prospector swept it into his sack and beat a hasty retreat, thinking he had been overpaid. It was more real money than he had ever seen. I have never heard of a case in which real money or greenbacks were offered that did not turn the trick for much less than the price asked.

Lack of croppings of commercial ore, lack of capital to develop, and the attitude of the engineer are the principal reasons for the disappearance of the prospector. I never could understand why the capitalist should ask the

engineer what a prospect is going to be worth when it is developed; he should consult a fortune-teller on such subjects. The practical man has developed more mines from the prospect stage than the engineer has, and the attitude of the employer toward the engineer is a result of this condition. The question should be: Will a property warrant the expenditure of a certain sum in development? Thus far I have heard of no man who can definitely value an orebody ahead of the churn-drill or the pick. The prospector has just cause for complaint about the way some engineers treat a prospect. I have offered a property, and the reply would be: "No, Bill Jones looked at it; there is nothing there". Or a corporation clerk will look through his files and you can be sure if your property is black-listed by adverse data there will be nothing doing. Why doesn't the engineer keep his mouth shut except to his employer and not injure an industry upon which his bread and butter depends? So far as the prospector is concerned he might as well quit and abandon the property, which has been done in a number of instances. I ask whether the practical man or the engineer can go on the witness-stand and swear whether a prospect will or will not make a mine. An engineer brought up this subject by saying: "Now that certain copper properties in Arizona have become mines, the adverse reports about them should be withdrawn". Who is going to discover the mines in the future if the prospector quits? The time is drawing near when there will be no new properties to examine. The engineer should foster legitimate mining. I have met engineers in the field who took an interest in instructing the prospector by giving him geological points about his property. The bigger they were the better fellows I found them to be.

The mines and croppings of commercial ore that stuck up out of the ground were found by the old-timers long ago and are now worked out. You can be certain that if you discover a new property in any section of the United States at present you are going to have to do some digging. If big corporations would stop and do some digging with a portion of the funds needed to keep engineers encircling the globe more mines would be discovered. The modern prospector should possess a field assay-outfit and have a thorough knowledge of geology. He should be able to make field tests for the rarer metals and other minerals that are of commercial value. A great deal of surface trenching is required in the softer inconspicuous veins that were formerly overlooked, as well as constant assaying. It takes from one to two years diligent searching and hard work to discover anything worth while; this requires more money than the average prospector possesses. Prospecting can best be conducted by the incorporation of a small exploration company that can keep a man in the field for a definite time. A great deal of valuable information as to where to look for a mine can be found in various books written by able geologists and in publications of the U. S. Geological Survey; schools of mines are also of great aid; but knowledge alone is not sufficient. If you are going to get a new

generation of prospectors in the field, more encouragement and financial aid must be given.

The prospector's greatest difficulty after making his find is to get financial aid. He cannot do enough development to interest the corporation engineer, and he has no funds to go to the industrial centres to offer his property for sale. It usually gets into the hands of someone in the nearest local town, or of a promoter. When his price is added to that of the prospector's the enterprise is too top-heavy to finance. A prospect will not stand the overhead expenses of fancy offices, clerk hire, and high-priced managers. Every dollar should be spent on the property. This can best be ensured by forming a corporation in which at least 80% of the money raised is expended in actual mining development. Many Eastern investors imagine they have bought mining stocks; as a matter of fact they have invested in gilt paper that is paying the personal expenses of some wild-cat promoter. These professional yeggmen have stolen thousands of dollars from the small investor and have absorbed all the capital that should be available for legitimate investment. A peculiarity of the tribe is that they can look you square in the eye, and lie for hours without batting an eyelash. The legitimate promoter, who makes possible the creation of new wealth, should be encouraged, not only in mining but in other industries.

It is well known that the large development corporations distribute their risks over several properties; so much is put into each one until a mine is discovered. All commercial business ventures are not a success. You would be fortunate indeed if you landed a big mine in the first prospect that was tested. An element necessary for success is that the man spending your money should understand his business. Thousands of dollars have been spent in building mills where there were no mines, and in running long tunnels where a prospect-shaft following the ore would have told the tale at a fraction of the cost. Other ill-advised operations are seen in the case of small companies with about \$15,000 capital that start to sink a shaft through 1000 ft. of rock to reach the ore-bearing formation, whereas \$150,000 or more is required to do the work. If your money is invested in one of those partly financed propositions you are sure to lose it. Something has been done for the next fellow that comes along, if it ever is completed. The engineer has the necessary training and should enter the field as a promoter; thousands of dollars could be saved. It is true that the development of prospects is highly speculative, but if properly conducted it is not more so than other speculative business.

The mining of precious metals in the United States is declining. At one time the prospectors of California and Virginia City, Nevada, saved the credit of the nation. Our country has grown from a swaddling infant to a huge industrial giant, who still has the trappings of childhood hung about him in the shape of red-tape and old laws. The apex law is a point in question. It was designed for the benefit of the apex attorney. No excuse can be found for such a law and there are as many reasons as a porcupine has quills that it should not exist.

I note that there is a great deal of discussion of the proposed new mining law. It seems that the few remaining prospectors have not enough difficulties in their path; new ones must be added. Some of the clauses are designed for the benefit of corporations and to the detriment of the prospector. If the object of the law is to discourage individual prospecting, it will accomplish the purpose admirably. Should the finding of new prospects be left to the corporations, our public mineral domain will be as silent as the Sahara desert. We have enough poorly enacted laws; what the prospector needs is legislation that will aid him. Our legislators should be patriotic and broad-minded enough to know that new discoveries will be made by individual effort as they have in the past. If more obstacles are put in the way, prospecting will cease.

Canada is encouraging the development of its mineral resources in many ways; the Government builds roads and trails for the prospector; a Government engineer makes a free examination of the prospect, and reliable data can be obtained by the capitalist who is looking for properties. In some Provinces the State grubstakes the prospector for an interest, and he can purchase powder and mining supplies at cost. If the American prospector had some of these advantages the mining industry would soon recover and the production of mineral wealth increase by the discovery of new mines.

Our national budget amounts to \$5,000,000,000 this year, but I have not heard of anything being done to help the prospector or the mining industry. It is up to our national representatives to do something for mining, for the welfare of the nation.

FRANK HALL.

Tonopah, Nevada, October 15.

Geological Mining

The Editor:

Sir—Philosophical definition of facts and beliefs involves much metaphysical reasoning, and consideration of the subject brings to mind an appreciation of the grounds upon which beliefs are based and the extent to which such are dependant upon the elements of time and knowledge. It is the part of wisdom therefore to recognize the dominant importance of principles.

The swing of events and of policies is due to the human tendency to disregard this conception. In some cases the underlying principle is so clear that but little variation results from the changing aspect of conditions; in others, however, existence itself is threatened.

It is curious that no more illustrative symbol can be used than the upbringing of a child by its parents. On what does the continuance of a parent's active influence depend, and how often does it continue more than a memory of childhood? So much for generalities.

Perhaps it is not too much to say that however clear may have been the scope and function of his profession to a mining engineer, it has taxed the powers of the best to present an ample and convincing statement of them to the public at large. I beg you, gentlemen of full persuasion,

to bear with me a moment; there is, I fancy, something to be said, even yet, upon this point, and I hope to make it clear. But first consider how many branches of the profession there are. We all know men who are unexcelled at reconnaissance work, at organization, at development, at equipment, but there are not many who excel at all of them. Remember that the public at large does not appreciate the inter-relation. Suppose that in course of time it became apparent that one of these branches had attained to such a degree of specialization as to encourage it to launch out as a separate profession; the public of that time might be excused for dissociating such work from its conception of the functions of a mining engineer.

It has been my privilege recently to hear an address by a well-known geologist and mining engineer who impressed upon his audience of mining engineers their duty of convincing the public by asserting themselves. In what way are mining engineers to assert themselves in such fashion as may be free from risk of variation due to changing conditions? I think that this may only be done through a clear enunciation of the principles underlying the profession, and I suggest that the following remarks upon the geological side of mining are pertinent to the inquiry.

In a recent paper by Augustus Locke that appeared in 'Economic Geology' the standing of the economic geologist was presented in a new light. It came as a surprise that so great a part of the theme should be based upon imperfect recognition of the geologist's work, and the first thought to be engendered was: Surely in these days no one can wish to belittle the achievements of the geologist or fail to acknowledge the basic influence of his discoveries.

But Mr. Locke is not concerned so much with these days as with the days to come, and not so much with the geologist's record to date as with the potentialities of his work in the future, so he broadens his view and reaches out into the fields executive for his appliers of geological science. Essentially the proposition is sound. Mr. Locke asks, from what source are such men to be drawn? I think the answer to that question is: from the ranks of the mining engineers. It may be that such an answer was intended. On the other hand, to some it may appear that the pendulum is swinging, and that the impetus of the justifiable recognition of his proved essential value might carry the geologist beyond the direction of useful endeavor.

Terminological discussion resolves itself into quibbling unless the aim is an enunciation of principles, but where such purpose is involved, the choice of methods of expression should not be lightly disposed of with a shrug and "What's in a name?" If the mining engineer is to assert himself before the public, his claim to recognition should be based upon the fundamental principles of his profession.

What is the mining engineer for, not only now, but always? One hesitates to show ignorance upon a subject that has been so ably discussed and expounded, but if it is true that a mining engineer is understood to be a man

whose training and experience fit him for the work of searching for, and the recovery of, minerals, with all that such a definition implies, from prospecting to finance, and if it is shown that ore-hunting is a profession for the geologist, what is the poor public to understand?

Excluding the coal and oil industries from the discussion for the moment, is it possible that our old friend 'ore' can be brought to trial again? Relegated to the text-books to describe metal-bearing minerals, may we let 'pay-ore' take a place in the definition of the mining engineer's functions, to the end that the economic geologist may be concerned with finding ore and the mining engineers with all that pertains to pay-ore? Or would it be better to coin a new term of 'mineral geologist'?

The above remarks are intended as an introduction to the suggestion that the relations of the studies of geology and mining are two-fold, and may be expressed by the terms 'mining geology' and 'geological mining', and in particular it is desired to lay stress upon the scope of the latter. The study of the habits of orebodies is so intimately associated with considerations of structural geology that it is unnecessary to emphasize the inherent need of geological knowledge for a mining engineer's guidance. The extent to which a close observance of structural facts may influence operations is an argument in favor of the possession of that knowledge by the men who are responsible for the conception and execution of policy. In one case recently noted, the imminent approach toward a zone of fracturing in the course of following an ore-shoot downward pointed to such changes in the conditions of oxidation and stability of the ground, as to warrant a complete change in a projected plant and in the methods of development and stoping. In another case, the gradual change in direction of orebodies, occurring in limestone near a contact with grano-diorite, from being parallel with the line of contact to almost right angles to it, as depth was attained, led to an appreciation of the increased influence of a series of crossing fractures as channels for the mineralization and to a change in the policy of prospecting development at a lower level. Again, the fact that concentration in disseminated copper orebodies in monzonite, lying between later quartz-porphry dikes, was found to occur at points where the course of these dikes was deflected, assisted the realization of the function of these dikes as indicators of lines of weakness, and gave rise to the exploitation of orebodies in quite other directions.

A mining engineer may not know the difference between an esker and an Esquimo; he may be even quite unprepared to dive into the depths of geological reasoning about periods and magmas. There is no call for him to drown himself—the mineral geologist will relieve him of responsibility on these scores—but he must possess an alertness, born of knowledge, that will enable him to grasp the significance of geological facts as they present themselves in the course of his work, if he is to fulfill the demands of the profession that seeks to stand before a public with confidence in its power and responsibility.

Vancouver, November 24.

HORACE G. NICHOLS.

The Education of a Mining Engineer

By T. A. Rickard

*When starting a discussion it is well to begin by defining the terms to be used. What is a mining engineer? The word 'mine' comes from the Latin *mina*, an excavation underground for destroying a fortification; later it meant a hole in which an explosive was placed for a belligerent purpose. Thus we have the word 'undermine'. Hamlet says:

"But I will delve one yard below their mines,
And blow them at the moon."

The original meaning of the word 'mine' survives in 'menace', a threat, and in 'minatory', a synonym for 'threatening'. The word 'engineer' likewise comes to us from the technology of the Roman soldier, for it is derived from *ingenium*, a military device, a war-engine, a battering-ram. The derivation is more evident in the French spelling, *ingenieur*. The idea of inventiveness survives in the word 'ingenious', and it fits the engineer, who is skilful in originating. The military connotation of the two words 'mining' and 'engineer' was revived during the recent war, when our professional friends and kinsmen came from the Yukon and California, from New Zealand and Missouri, from the remotest corners of the earth, to join in fighting in behalf of the great cause. One member of our profession, Ralph S. G. Stokes, who in the first week of the War went from New York to London to enlist as a private in the British regiment of Royal Engineers and rose by force of merit to the rank of Lieutenant-Colonel, served as 'Controller of Mines' in Flanders; he supervised the preparations for the tremendous 'blow', or explosion, at Messines on June 6, 1916. That was a truly great 'mine' in the original sense of the word.

You will recall Mark Twain's definition of a mine as "a hole in the ground owned by a liar". The definition is amusing; but many an untrue word is said in jest; the liar is not the honest prospector of whom we think as the owner of a young mine, but a much less responsible person, the promoter whose regard for truth is so great that he rarely uses it, the so-called fiscal agent who converts an honest excavation into a purring 'wild-cat', with claws—and whiskers! I insist that the mining engineer is connected with a legitimate form of industry, the main purpose of which is to make money by winning the valuable metals and minerals from their rocky matrix within the crust of the earth. The object of mining is not—as is supposed by some—to spoil the scenery of the beautiful parts of the earth or to afford employment to the sons and nephews of the favored few. Nor is it the primary purpose of mining to obtain cross-sections for

the elucidation of geologic problems or to gather data concerning the increment of temperature in depth. No; the motive of mining is neither academic nor altruistic; it is, in plain English, to make money, honestly, by producing the metals and minerals essential to the very existence of our material civilization. Engineering has been defined as "the art of directing the great forces of Nature for the use and convenience of Man". That is the motto of the Institution of Civil Engineers in England. On the United Engineering Societies building in New York it is written: "Engineering, the art of organizing and directing men, and controlling the forces and materials of nature for the benefit of the human race". This is idealistic, and not wholly true, for the art of engineering is applied usually not with benevolent purpose but for honorable gain—to the engineer himself, to his employer, to the community, but rarely for the express benefit of the human race. That is too large an order.

Again, it does not seem to me correct to define engineering as "the art of organizing and directing men". That is pre-eminently the art of the politician! A man can be a great engineer without ever taking charge of the men that do the work of construction. He is better for the experience, but it is not essential to his art. However, when we do think of mining engineering as used for the benefit of mankind, we think of Herbert C. Hoover, who applied his experience as a manager of mines to a great humanitarian task. He fed ten millions of Belgians and French at a total administrative expenditure of less than half of 1%—to be exact, 0.42%—of the cost of the entire operation. That reminds me of a story.

Several years ago Mr. Hoover was crossing the Atlantic and happened to sit at table next to a British gentlewoman of the Early Victorian type. After passing the salt and offering the Worcester sauce once or twice, he became acquainted with her, as one does aboard ship. He told her of his travels in China and Mexico, in Australia and Burma; and she found the young man both agreeable and interesting. Near the end of the voyage, by which time they had become pleasantly acquainted, she asked him, "What are you, Mr. Hoover?" He answered, "An engineer". "Oh!" she exclaimed, "I thought you were a gentleman!" She thought an engineer was an engine-driver; and probably to her a gentleman meant a person without visible means of support. If she lived to the time of the Great War and read of Mr. Hoover's achievements as dispenser of nutrition in Europe and as Food Administrator in the United States, she may, in her quiet home in rural England, have awakened to the fact that an 'engineer' may

*An address delivered on the occasion of the semicentenary of the Missouri School of Mines, at Rolla, Missouri, on November 5.

be several kinds of a man, and sometimes, as Shakespeare says, "he is a proper man's picture".

Well, what is a mining engineer? I know of only one definition that is sufficiently comprehensive: he is a man that does the work of a mining engineer, namely, the management of mines, the examination and appraisal of them, the work of surveying underground, the planning and devising of ways and means for winning ore. A degree from a University or a School of Mines does not make a mining engineer; the degree merely certifies to an adequate scholastic preparation for the work. Many graduates from mining schools have never practised the profession for which they were prepared; they have become brokers or druggists, for example. On the other hand, sundry brokers and druggists have dropped their original vocations and learned enough of the art of mining to examine mines, to appraise them, and even to manage them. When they did that they were mining engineers—some of them may not have been the best of their kind, but they earned the designation by doing the work. I am reminded of the New York City boy who was on a summer excursion in the country and asked the teacher, "What kind of a boid is that?" You know that the boys from the East Side say 'thoity-thoid' for 33rd, 'foist' for first, and 'boid' for bird. So this boy asked, "What kind of a boid is that?" The teacher said, "That is not a boid, it is a bird". "But", replied the boy, "it makes a noise like a boid." It did. So a man that makes a noise like a mining engineer—talks like one, does his work like one—is a mining engineer, whether he be duly certified or not. In some States he must be licensed, and if he can show a diploma it is easier for him to obtain a license—for example, a shorter period of apprenticeship is required—but otherwise he has the same chance as his friends—for they are his friends—whom we may term 'diplomatic' because they have diplomas. It is well that this should be so, for our American ideal is the equality of opportunity; we recognize no privileged class, even of scholars; it would be unfair to debar any young man from reaping the reward of the training that is acquired in irregular ways, by night-study, by association with helpful seniors, by reading, observing, and experiencing the things requisite for the development of capacity as a professional man. Several honored members of our profession entered it by the side-door—not the back. One distinguished veteran was a carpenter and the son of a carpenter, with none of the advantages typified by such an institution as the Missouri School of Mines. Another began life as a sailor; a third, as an accountant; a fourth, as a botanist. I am speaking of men now acknowledged to be in the first rank. Many, of course, began life as laborers in mines and mills; starting to do manual work when their more fortunate comrades of the future were still at school. The chief difference between them and the 'regulars'—those who underwent the conventional training—is that they acquired their knowledge more slowly, more laboriously, and they reached positions of emolument comparatively late in life. The chief purpose of school or college is to learn how to learn. The preparatory school to which I went has for its motto

"*Non scholæ sed vitæ discimus*". "We learn not for school but for life." It is perfectly logical, for example, when licensing a man as an engineer or admitting him to membership in a professional society, to require as a qualification more years of responsible service from a non-graduate than from a graduate, because an unschooled mind is slower to apprehend than one that has been trained.

Here we come to the definition of education. Education is the process of educating; the word is derived from the Latin *e*, out, and *ducere*, to lead; it means the leading out or bringing forth of the innate powers of an individual; it means the bringing up or rearing of a child; and it applies to the children of a larger growth, to us all, whose education continues throughout life, until our mental faculties become atrophied. 'Live' and 'learn' are conjoined advisedly, for when we cease to learn we may as well die. It is said that John Richard Green, the historian, asked that his epitaph might be, "He died learning".

So we have considered the meaning of the terms used in our subject, the education of a mining engineer. It means the proper training of the young man who intends to do the special work that is required in connection with mining. Mining is an art, or a skilful method of doing things; to it the various sciences are applied with a view to improving the method. So we learn mathematics, mechanics, physics, mineralogy, and geology; the knowledge obtained is less important to us than the manner in which it is obtained, for what we learn in a school or a college is of small consequence, and soon forgotten, as compared with the training of our mental faculties so that we may be able to think clearly, observe accurately, and state truthfully. This we cannot do unless we use our language properly, for truthfulness of statement depends upon the proper use of the words that are the symbols of thought. Therefore we engineers should learn how to speak and write—particularly to write—intelligently and intelligibly. Of all the instruments of precision used by a mining engineer the one that he uses most is his own language—the language that came from the old country, from Chaucer and Spenser, from Steele and Addison, from Shakespeare and Milton. It is a beautiful language and a flexible instrument of expression. Our mining engineers are well grounded in the various 'ologies'; they have been well drilled in the requisite number of sciences; but they do not appear to see the prime necessity of acquiring the one accomplishment without which the others may prove ineffectual. I shall speak plainly.

During recent years public attention has been drawn to the need of teaching English, more particularly to those who are undergoing training for an engineering career, because it has become recognized that our profession is sadly lacking in the ability to speak and write effectively. We—you and I—may be especially critical of this defect because we know that it is necessary to use the language correctly in describing or discussing technical operations and ideas; but defective English is common to our American youth generally—boys and girls

alike. Much has been said on the subject and many are the causes to which these shortcomings are ascribed. I venture to be frank with you in stating that one cause is our democratic way of living. Do not mistake me; I am keenly in sympathy with the democratic idea; I believe it to be the best stimulus for the further progress of our civilization, and I believe that the destiny of our country is to develop the idea of democracy for the benefit not only of ourselves but of the world at large. If we are intellectually honest, however, we must recognize the fact that democracy levels down as well as up. For example, you and I, the audience and the speaker, belong to the professional class, a class that is differentiated not by wealth but by education, by the possession and use of brains that have been trained for our several vocations. Our children go to the public schools, which follow the democratic custom of allowing all children, of whatever class, to share the same instruction. I use the word 'class' as the equivalent of 'type', not to signify any recognized social stratification as in Europe. Our children at school sit side by side with others that come from homes where defective English is spoken, from the homes of aliens who have not learned to speak our language properly, from the homes of those of our own native stock who did not go to school in their youth or who for other reasons are illiterate. The children sit together and they play together, in good democratic fashion; they acquire the same habits of speech; the young negro, the young Japanese, the young Italian, the grocer's boy, the hod-carrier's son, the laborer's girl, the parson's son, the professor's daughter, all sympathetically and naturally acquire the same kind of language. The result is that those who speak it badly learn to speak it less badly, whereas those who speak it well learn to speak it less well. That is why the children of our professional men do not speak as well as their similars in England, whereas the children of the laborer, the hod-carrier, the plumber, and the grocer speak and write much better than their similars in the old country. There the sons of professional men go to school with the sons of other professional men—to schools that resemble our private schools—where they do not associate with those reared in illiteracy. The effect is to perpetuate a social distinction; to make good speech a mark of class. We obliterate the class distinction, we sacrifice the facility for acquiring correct speech to the supreme ideal of our democracy, namely, an equality of opportunity. I do not cavil at it; it is worth while, but we must recognize the penalty—a small one relatively—that we pay for the sake of our ideal.

Next comes the question, should we continue this system of education in common although it have a result prejudicial to a part of the community? Speaking broadly, it seems to me that we should continue to sacrifice the literacy of a few for the sake of educating the many, and that a division of our children according to class or vocation would be a step backward; but we can remedy the obvious consequence by insisting upon more and better teaching of English in our schools and universities. For example, our mining schools should make it a part of their duty to improve the speech and writing

of their students by maintaining a class in English at least for the freshmen, as most of them do already, and by requiring a good standard of writing throughout the successive years spent in technical education. An examination paper in mechanics or mineralogy, in physics or geology, should be required to reach a standard not only in the knowledge of the science but also in the art of expression. It may be said that it is no part of the duty of a School of Mines to teach English, which should have been taught to the student in the high-school. The answer is that we face a condition, not a theory; and if the students come insufficiently trained in a matter so important as the use of their language, it is only fair and wise to give them the necessary training before it may be too late. I note that in this School of Mines three hours per week during the first and second years are allotted to English; moreover, a class in technical writing is maintained for the senior students; in this respect you set a good example.

Next I shall refer to another cause of poor speech and bad writing. Many of our young men seem to think it democratic and American to talk in a slovenly way; and the habit, I think, affects their writing. When college graduates start to work at the mines they desire to seem 'practical' as soon as possible, and in order to be friendly with the workmen they are deliberately careless in their speech, avoiding nicety of expression as if it were effeminate. Some, I am sorry to say, appear to think it necessary to imitate the 'mucker' and acquire methods of speech common to illiterate workmen, as if it were manly, as if in protest against the high-brow or academic cult. In consequence, many young fellows from homes of refinement, the sons of well-educated parents, the graduates of great colleges, the pupils of distinguished scholars, talk and write deplorably. It is a huge blunder to suppose that such a failing is either democratic or American. To be either one or the other it is not necessary to be unseemly in manner or uncouth in speech; on the contrary, I say with confidence that a young American democrat should aim to be as courteous in manner, as decent in bearing, and as correct in speech as any aristocrat of the old world, but he should be just 15% more intelligent. It is intelligence that classifies men in a democracy. The greatest democrat of all, Abraham Lincoln, did not think it improper to speak and write carefully. In his public utterances, spoken or written, he endeavored to use good English; indeed, he developed a skill that made his speeches and writings models of classic excellence. It remains a perpetual miracle that a man with so few educational advantages should have acquired such a mastery of the language that the best of his utterances are unexcelled in the literature of our race. The Gettysburg speech and the Second Inaugural address are, and will remain forever, models of exquisite diction and consummate oratory. How did Lincoln acquire this remarkable skill? First, he had few books to read, but they were of the best: the Bible, 'Pilgrim's Progress', Shakespeare, Aesop's 'Fables', and Blackstone. His mind sought good company. He walked miles to borrow a book on grammar and he gave his spare

time to it while tending the village store. I like to think of young Lincoln lying at full length on the counter of Greene's store at New Salem, his head propped on a pile of calico prints, while he read 'Kirkham's Grammar', or sitting in the shade of a tree while he studied Blackstone's 'Commentaries', which he found among some discarded papers at the bottom of a barrel. He did not have to read the yellow press of today or even the dialect stories in our current magazines; so he escaped the contagion of jargon. His Gettysburg speech contains only three words not in the Bible; they are 'continent', 'proposition', and 'evil', but all three are to be found in Shakespeare. He drank freely at that well of English undefiled, the King James version of the Bible. The language of the Bible and of Shakespeare is the best part of our familiar speech. Here I may mention that now no student at Harvard can receive his degree without passing an examination in the Bible; indeed, the authorities at Cambridge rank the Bible and Shakespeare as "two works of literature without which an adequate appreciation of English letters is impossible". This rule is not prompted by devotional or religious motives, but by the same eulogical considerations as caused Huxley to advocate the reading of the Bible in the public schools of London. To good books Lincoln owed much; but in part his astonishing skill was due to another cause, only recently made known. He lived in an illiterate community and among people who spoke badly; when listening to his associates and hearing their yarns in the local store he noted their inability to express themselves successfully; he thought about it, and made the experiment of putting their sayings into more careful language; he would go home and write down the story that had been told clumsily and then proceed to put it into better words; that is, he edited what his friends had said. Thus he gained skill in the use of speech; he realized that there was a technique of language and he set himself to acquire it; and he did acquire the technique so thoroughly that his words, warmed by his genius and glorified by his spirit, will echo forever down the corridors of time.

So, gentlemen, no American can say that it is undemocratic to speak like a gentleman or to write like a scholar. On the contrary, we technical men, who have to deal with subjects requiring precise presentation, should be particularly desirous of using the instrument of expression with care. The difference between good and bad writing is chiefly the difference between being careful and being careless. It is not difficult, if one desire to do so, to learn to write respectably. To acquire the art of Lincoln, of Ruskin, or of Stevenson there is needed more than care, more than conscious effort; but ordinary skill, sufficient for most of us, can be acquired by anyone willing to take pains. Genius has been described as one part inspiration and nine parts perspiration; we can be nine-tenths of a genius if we have the capacity for working with sincerity of purpose. Only recently I overheard a woman say to her companion in a suburban train: "I'd like to be able to write clearly without stopping to think about it". She was one of many, of those who would like to do a thing well without the trouble of thinking; but it cannot

be done in respect of anything to which thought is essential. However, she was not unlike some of my young friends in the mining engineering profession who use the chisel of language as if it were a screw-driver. It is astonishing how many graduates from universities will write: "The data *is* sufficient", "the propaganda *are* objectionable", "the agenda *was* printed". An Assistant Principal in a School of Metallurgy wrote to me that he observed "*this* same phenomena in other kinds of glass"; and, as if to show that the error was not inadvertent, he repeated it twice. When I wrote in a kindly way to warn him, he apologized, but intimated that he was rather pleased with his skill in writing. How often we read of proposals to tax "the necessities of life", as if being subject to necessities were not sufficient cause of unhappiness without our being taxed on account of them. The tax is levied on the 'necessaries', the staple articles, not the necessities that they satisfy. This use of the abstract instead of the concrete is characteristic of the windy utterances of politicians. It reminds me of the Babu—a half-educated Hindoo—who, when declining an invitation on account of the death of his mother, wrote: "Regret I cannot come, the hand that rocked the cradle has kicked the bucket".

Well, I have said enough concerning one phase of the education of mining engineers; if I say more you will charge me with attempting to make journalists of them. After all, before one writes one must have something to say. As to that, I doubt if any men have more opportunities to gain information and to see the world at large than the members of our profession. American engineers have gone to the remotest corners of the globe, following the lead of their British comrades. In South Africa and Western Australia they have made their mark; in Canada and South America they fill today many of the chief positions in the management of famous mining enterprises. They have participated in the development of the principal mines of Siberia. Just now the shrinkage of capital and the temporary abatement of the spirit of mining adventure have restricted their activities abroad, but the time is coming when they will be called again in large numbers to foreign fields of activity. The reason they are wanted is because they are efficient, particularly in their clear-headed appreciation of the business side of mining, plus an intimate acquaintance with the latest technology. [May I digress for a moment: when first I went to Colorado, 36 years ago, I made the acquaintance of a number of Columbia men, who proved exceptionally successful in their profession. I used to wonder why they had done so well; I did not impute the result to exceptional teaching in mining or metallurgy; in later years I have put it down to the fact that they came from Boston and Brooklyn, and that they underwent a severe grueling in mathematics at the hands of Professor Van Amringe. Indeed, he seems to have played the part that your Professor Dean appears to have filled in this School of Mines.] The United States can boast many excellent mining schools—that of Missouri is one—but the reason why our men are effective is due to the larger fact that the United States is a great mining country; indeed, it

is a continental area in which are found many mining regions of diversified character, yielding nearly every one of the metals and minerals required by our material civilization. We may be short of tin and antimony; we may not possess deposits of chrome and manganese so generous as those to be found elsewhere; but in a broad way our country is exceptionally endowed with mineral resources. Therefore it offers a post-graduate school of mining unsurpassed in the world at any period of human history.

Another condition favorable to the development of competent mining engineers in the United States is the social status of our profession. If one of you were to take a young Englishwoman in to dinner and ask her what was her idea of a mining engineer, she would say, probably: "A somewhat nomadic person connected with queer doings on the Stock Exchange". An American girl would reply differently; she would, I believe, intimate that the mining engineer was a half-back with a scientific education, competent to dig gold out of the ground and to manage men at least as well as the colonel of a regiment. In England the mining engineer ranks socially below the officers of the army and navy, below the barrister and physician, below the people who live on the rents from land and the coupons from bonds; indeed, the profession is so young compared with the survivals of an ancient system that it has not yet come into its own. In our country the mining engineer may call at the White House and shake hands with the President as a matter of course. When Cecil Rhodes established his scholarships at Oxford he aimed to promote international goodwill, but, although he had gained his wealth in mining, it did not occur to him to found a College of Mines at Oxford. If he had done that, he would have accomplished a great benefaction for the profession and for the mining industry of the British empire, but such an educational foundation would have been a complete departure from British tradition—especially at Oxford, "the home of lost causes and forsaken beliefs". In our own country the chief mining schools are attached to, or are integral parts of, our universities. That is as it should be. Most of our engineers have enjoyed some of the advantages of a university education along with their technical training. It is becoming recognized that the preparation for a bread-and-butter dependency, for a salaried 'job', is not an education in its true sense, and that to make men of real worth, likely to be happy and useful, prepared to do the work of the world as effective citizens, there must be some culture, some bringing forth of the faculties that distinguish *homo sapiens* from the rest of the *genus homo*. "Man does not live by bread alone." If our great experiment in democracy is to succeed it will be by reason of "the moral worth and intellectual clearness of the individual citizen". The mob cannot help, nor will the yellow press; education can do it by bringing the right men into leadership. The University of Missouri and its School of Mines can forward the consummation of a great ideal, and I feel confident that they will.

It has been my privilege to know most of the leading mining engineers of the world, in this and in other coun-

tries, during the last thirty years, and I am informed concerning the careers of many of them. In a broad way they are an exhibit for the educational methods of the last quarter of the nineteenth century. What can we learn from their biographies?

In the first place, the successful mining engineer—the man who has won the esteem of his fellows and established himself in an extensive and lucrative practice as a manager of mines or as a consulting engineer—is not always a college graduate nor even a man trained in a mining school. About one in seven has missed these advantages. I use the word "missed" advisedly, for if he had been better educated he would have been even more useful and efficient. The lack of educational advantages and the comparative poverty of his parents to which this was due have had the effect, however, of compelling him to work harder and have tended more strongly to develop his character—to make him industrious and self-reliant. To be given a good education and to start life without the urgent need of earning a living is not always the best thing for a young man, especially if he lack initiative and ambition. In a democracy, as in other types of social organization, it will be found that those who are born with a silver spoon in the mouth are likely to die with gold filling in the teeth, without having accomplished anything more decorative. It is proper that we should admire the man who makes his own way. For example, your own most distinguished alumnus started life as a poor orphan lad, reared on a small farm; he earned money for his schooling by hard work; by dint of personal effort he won his way to this School of Mines and here obtained the lever by which he opened the world oyster, in the shape of the greatest copper mine on this continent. To give an education to such men is the finest investment a nation can make.

When I review the life-histories of the men whom I admire and respect I realize how much their university education has expedited their mental development and hastened their arrival at positions of influence. Only men of extraordinary force of character have been able to achieve success without such help, and, it is sad to say, they represent the few survivors of hundreds who failed for the lack of such help. In the days to come the chances of the unprepared will be even less, for the demands made upon engineers, in the way of scientific training, will become increasingly exacting.

Much of men's success seems to be due to accident. This one was lucky in making the acquaintance and arousing the personal interest of a leader; that one happened to be on hand when a particular post had to be filled in a hurry; another had the special experience required for a special piece of important work at a given time and place; a fourth had personal qualities that won the goodwill of the president of a company or the manager of a big mine—and, needless to say, gentlemen, I rate the manager of a mine above the president of a company. So it seems as if much of life were fortuitous; as if men became successful through accident. This is a superficial view; on the contrary, it will be found, on closer scrutiny, that the success is due to the man being

ready for his chance, to his having prepared himself for many contingencies, so that when opportunity knocked at the door he was ready to rise and give instant welcome to the visitor. Our own deeds are our doomsmen.

"There is a tide in the affairs of men,
Which, taken at the flood" [to which Byron
added]—"you know the rest,
And most of us have found it, now and then;
At least we think so, though but few have guessed
The moment, till too late to come again."

Some, like children, only wade in the shallows and so fail to feel the greater impulse out at sea; they fear to swim in deep water and are left behind, high and dry. Our life is as "the sands betwixt two tides".

The difference between men is chiefly the difference of character. Education develops character—that is the very essence of education. A man of character goes through the shoals of circumstance as a ship directed by a captain with a compass and a chart; a man lacking character is like a ship without control that drifts upon the reef and suffers shipwreck. Herbert Spencer said that "of all the ends to be kept in view . . . all are unimportant compared to the end of character-making. This alone is national education". In the last resort mere cleverness will not take a man far; there is needed something more dependable, and dependability is character. A man of character will act in the same way under the same conditions. Give a man of character a liberal education and he becomes the finest product of our civilization. It is the product that an educational institution such as yours aims to give to the United States—worth more than much fine gold or a million tons of copper. A liberal education is the aim of all true scholastic effort; but there is no complete agreement as to the necessary curriculum. After all, a liberal education is the product of an ideal that transcends the curricula of the schools. Permit me to quote from the greatest expositor of the nineteenth century, Thomas Henry Huxley:

"That man, I think, has had a liberal education who has been so trained in his youth that his body is the ready servant of his will, and does with ease and pleasure all the work that, as a mechanism, it is capable of; whose intellect is a cold-logic engine, with all its parts of equal strength and in smooth working order; ready, like a steam-engine, to be turned to any kind of work, and spin the gossamers as well as forge the anchors of the mind; whose mind is stored with a knowledge of the great and fundamental truths of Nature and of the laws of her operations; one who, no stunted ascetic, is full of life and fire, but whose passions are trained to come to heel by a vigorous will, the servant of a tender conscience; who has learned to love all beauty, whether of Nature or of art, to hate all vileness, and to respect others as himself."

Huxley was the Dean of the Faculty of the Royal School of Mines—my alma mater—a school that was royal not by reason of kingly patronage but because it had for teachers such men as Huxley, John Tyndall, Lyon Playfair, Edward Forbes, and John W. Judd. Gentlemen, permit me to transmit to you this description of a liberal education as the greeting of the Royal School

of Mines of London to the School of Mines of Missouri on the occasion of its 50th anniversary.

Pulverized Coal

Firing with powdered coal has many characteristics to recommend its use. Its principal advantages over hand- and stoker-firing lie in the comparative ease of conveying it to furnaces and in its practically complete combustion with little excess air in close contact with the material to be heated, thus avoiding the convection, radiation, and excess air-losses which accompany hand- or stoker-fired furnaces placed outside reverberatory and many other furnaces. For this reason its most successful field of use has been for those purposes where it has replaced externally-fired furnaces. For purposes such as steam-raising where the burning coal can give up heat directly by radiation to the boiler-heating surface, there is therefore less opportunity for reducing the fuel consumption by burning powdered coal instead of burning coal on a grate, since the losses which may be reduced by substituting powdered coal-firing for hand-firing or stoker-firing are those only which are due to incomplete combustion and using excess air. These losses, however, are not inconsiderable, says John Blizard, of the Department of Mines of Canada.

Before powdered-coal firing may compete successfully with grate-firing it is obvious that the gain due to the smaller consumption of powdered coal must offset the cost of preparing, conveying, and burning it. When firing with powdered coal, ash is blown into the furnace, out through the stack, and, with some badly-designed furnaces, out through openings in the furnaces. It may also form a troublesome slag, and fill up the flues so as to impede the draft. Nor, on the whole, can powdered-coal plants be said to be clean. There are fairly clean powdered-coal plants; but generally a plant using powdered coal is dirtier than a grate-fired plant. At one plant using it, and visited by the writer, the quantity of coal blown out from furnaces was so objectionable in rivet-heating furnaces, with the air-suspension transport system, that it has been replaced by oil-firing, in spite of the fact that powdered coal was cheaper fuel than oil. At another plant where powdered coal delivered by the air-suspension transport system was used for forge-furnaces, it was found that the increased cost in repairs to presses and cranes near the furnace, due to powdered-coal firing, amounted to 23c. per ton, and the additional cost for repairing furnaces to 15c. per ton. Nor has powdered coal always given as satisfactory a heat as stoker firing. At one plant visited, they had abandoned powdered coal for firing forge-furnaces, because either the gases passed through the furnaces at so high a velocity that it was impossible to obtain a soaking heat, or, if retarded by closing the damper, ash was blown into the mill. It must not be understood from the foregoing that powdered-coal installations have proved unsuccessful. On the contrary, they have generally proved most successful. The use of powdered coal has seldom been discontinued after once being adopted.

Proposed Revision of the Mining Law

A Report Adopted by the Mining Committee of the Commercial Club of Salt Lake City

The so-called Arentz Bill, introduced in the House of Representatives on July 12, 1921, by S. S. Arentz, of Nevada, provides for the revision, amendment, and codification of the laws of the United States relating to the location of mining claims on the public domain. One of the best analyses of the proposed bill, which has been subject to much discussion in the Western mining States, was written by Mr. James H. Ball, chairman of a subcommittee of the Committee on Mining of the Salt Lake City Commercial Club. The report is reproduced herewith almost in its entirety:

SECTION 1 provides that the Act may be cited by the short title of 'United States Mining Act'.

SECTION 2. Lands valuable for minerals are reserved from sale, except as otherwise expressly directed by law.

SECTION 3 provides that all valuable mineral deposits in lands belonging to the United States shall be open to exploration and purchase by citizens of the United States, and those who have declared their intentions to become such. Since rights in lands containing potassium, coal, phosphate, sodium, oil, oil-shale, and gas are acquired under the terms of other Acts of Congress it is provided that these deposits shall be unaffected by the Arentz Bill; neither does it pertain to withdrawals of public lands which have been or may hereafter be made.

SECTION 4 prescribes the manner in which proof of citizenship may be made.

ARTICLE 'A' OF SECTION 5. By this article it is provided that every claim upon unsurveyed lands shall be located in the form of a square, laid out on cardinal lines, conforming to the system of public-land surveys; and that claims upon surveyed lands shall also conform to the subdivisions of the public-land surveys. In our judgment, in order to perfect a valid location, this requirement as to the manner of location would make the employment of a surveyor necessary, and in that way a hardship would be worked on the average locator of mining claims, with the result that the making of mining locations would be discouraged, except as to men of means or wealthy corporations.

By this article it is also provided that the size of a full claim shall be 40 acres; but claims containing 10 acres may also be located in the form of a square. Under the present law a claim may equal but shall not exceed 1500 ft. in length along the vein or lode, and may extend 300 ft. on each side of the middle of the vein. It is not necessary under the present law that the locator take this maximum area, since at his option his claim may be shorter and narrower. For instance, it may be 1000 ft. in length and 200 ft. in width, but under the Arentz Bill a claim containing 10 acres and in the form of a square,

laid out on cardinal lines, seems to be the minimum in acreage. Under such circumstances we do not see how a locator can conform his location to a long and irregular outcrop without including and paying for unnecessary acreage.

ARTICLE 'B' OF SECTION 5. This article provides that a discovery of valuable mineral shall not be necessary in order to locate and hold a mining claim; and that a claim located without discovery on land classified as mineral, may be held for five years without discovery, after which time it shall be open to re-location. It is also provided that upon failure to make discovery within the period of five years a locator shall have the right to hold the claim or claims for further annual terms not exceeding five years, by payment annually in advance of \$50 for each acre, or fraction thereof, which annual payment shall be in lieu of any further requirements for assessment work.

ARTICLE 'B' OF SECTION 5 should be considered in connection with Article 'B' of Section 6, which provides that on each claim until patent has been issued, not less than \$5 worth of labor shall be performed or improvements made during each year for each acre, or fraction thereof, comprised in such claim; or that in lieu of the performance of such labor a sum calculated at the rate of \$5 for each acre, or fraction thereof, may be paid each year into the United States Land Office for the district.

From careful consideration of the provisions just alluded to, it will be perceived that by virtue of Article 'B' of Section 5, a locator, without any discovery whatever, and without a penny's worth of work leading to discovery, may obtain the exclusive possession of a claim or group of claims for a period of 10 years. True, under the requirements of Article 'B' of Section 6, he must, during the first five years, either expend in labor or improvements, \$5 per acre for each acre, or fraction thereof, contained in his location, or pay into the Local Land Office an equivalent in cash; but whether he shall do the work or deposit the money in the Local Land Office is a matter which is left to the discretion of the locator. Possession during the last five years of the 10-year period does not contemplate the performance of annual assessment work, since it is provided that the privilege of holding the claims for this additional five years may be acquired by the "payment into the Local Land Office annually in advance of \$50 for each acre or fraction thereof, which annual payment shall be in lieu of any further requirement for assessment work".

Thus it will be seen that for at least ten years land may be held without anything whatever having been done during that period toward the development thereof, or the extraction of the minerals supposed to be contained

therein. We do not think it is advisable to amend the present law so as to make it possible without doing the annual assessment work thus to hold lands classified as mineral, when, as to all mineral lands, the performance of development work and the extraction of the minerals is the thing desired and to be encouraged. In addition to the retardation of the actual development work, the proposed amendment would in our judgment work a hardship on miners who depend for a livelihood on the employment arising from the work usually done and the improvements usually made in the performance of assessment and patent work.

ARTICLE 'C' OF SECTION 5. This article provides that upon making discovery, the locator shall file in the Local Land Office a sworn statement as to that fact, showing the nature thereof; and that upon verification of such discovery by a United States Deputy Mineral Surveyor, (which examination shall be at the expense of the claimant) the owner of the claim shall be entitled to hold it under the same conditions as though discovery had been made before the original record was filed in the Land Office. Discovery effected by drilling more than 100 ft. in depth may be established by affidavit of at least two persons thoroughly acquainted with the facts, which proof shall be accepted as *prima facie* evidence of discovery.

Under the present mining law the locator does not incur any expense in proving his discovery. Before issuance of patent the Government, through its field division, makes an investigation without expense to claimant for the purpose of satisfying itself that the necessary discovery has been made and that the required amount of patent work has been done. It appears to us that the provisions of the present law are much more simple and satisfactory than the method contemplated by this article, which method seems both cumbersome and expensive.

ARTICLE 'D' OF SECTION 5. This article provides that where no proceedings have been initiated in the United States Land Office to acquire a non-mineral estate in public land, classified as non-mineral, mining claims may be located thereon with or without discovery.

We fail to perceive any necessity for such a provision, since under the present laws provision is made whereby mineral land improperly classified as non-mineral, may be subjected to proper classification and patented as mining land. We fear that under the pretext of locating mining claims, lands would be tied up for purposes foreign to mining.

ARTICLE 'E' OF SECTION 5. By this article it is declared that one discovery shall be sufficient to support the holding and patenting of a maximum of four contiguous full claims aggregating 160 acres (if held in common ownership), or 16 contiguous 10-acre claims aggregating 160 acres, if held in common ownership.

Under the present law, a discovery is a condition precedent to the validity of every mining claim. Annual assessment and patent work for a group of claims may be performed on one claim of the group, provided the work done on the selected claim is calculated to accomplish the

development of the group, under a scheme or plan for their common development. But nevertheless a discovery on each claim of a valuable deposit of mineral is essential. Under the change contemplated by the Arentz Bill, a discovery on each claim of a group will be unnecessary. Four contiguous full claims of 40 acres each, or 16 contiguous 10-acre claims may be held and patented by virtue of one discovery on any one of the group. This provision should be carefully scrutinized. In size, a 10-acre claim is exactly comparable with one of our large Salt Lake City blocks. Assume for convenience of consideration an area of four of our city blocks in width by four in length, or from Main street to Fourth East street, east and west, and from Brigham street to Fourth South street, north and south, which in acreage would be equivalent to sixteen 10-acre claims. Under the proposed change an area equal in size to 16 of these large city blocks may be held and patented on the strength of one location made, say, far up in the north-east corner of this large tract, even though as a matter of fact $\frac{1}{16}$ of the area was absolutely valueless as mining land. But this is not all. There is no limit to the number of lode claims which one person or a corporation may locate, and consequently group after group containing sixteen 10-acre claims would in this manner be subject to acquisition by any one having the capital necessary to pay the purchase price of \$5 per acre.

We do not think it should be made so easy for any one to abuse the privilege of acquiring mining property.

ARTICLE 'F' OF SECTION 5. This article deals with the location of placer claims in Alaska, and consequently will not be discussed.

ARTICLE 'G' OF SECTION 5. By this article the time after the date of original location within which entry and payment shall be made for mining claims located after the effective date of the proposed new law is fixed.

ARTICLE 'H' OF SECTION 5 provides that in all cases of an application for a patent to mineral land a discovery shall be a condition precedent.

ARTICLE 'A' OF SECTION 6. This article deals with the question of marking the boundaries of mining claims and the posting of notices of location. In the interest of all concerned we believe that Congress should fix a definite minimum requirement as to the marking of claim boundaries; and in this connection, since most mining claims are located on lands, the surface of which is quite irregular, we are of the opinion that a permanent monument at each corner of the claim, as well as one in the centre of the end- and side-lines, would prove to be a just and satisfactory requirement.

ARTICLE 'A' OF SECTION 6 also provides that all notices of claim location, whether located before or after the effective date of the proposed bill, shall be recorded in the United States Land Office of the district in which located. The duty to record and the expense thereof rests with the locator. While for the reasons hereinafter stated, we are of the opinion that it is very desirable that a complete record of all mining claims should be available for inspection at the Local Land Office, we do not believe

the duty to record or the expense thereof should be cast upon the locator. Concerning the desirability of having in the Local Land Office a complete record of all mining claims in the district, we call attention to the fact that quite often officials of the Local Land Office entertain applications of one sort or another affecting lands which are covered by valid mining locations. For instance, as the law now stands, the owner of a perfectly good and valid mining location may find that under the Oil Leasing Bill a permit has been issued authorizing someone else to prospect the same lands. This situation would have been obviated had there been a record in the Local Land Office of a notice of location covering the land embraced within the prospecting permit.

ARTICLE 'B' OF SECTION 6 provides for the performance of annual assessment work, or, in lieu thereof, the payment into the Local Land Office of an equivalent amount of cash. We have previously discussed this subject.

ARTICLE 'C' OF SECTION 6 provides that upon failure to comply with the conditions as to annual assessment work or payments, the claim shall be open to re-location in the same manner as if no location of the same had ever been made.

ARTICLE 'D' OF SECTION 6 provides the procedure under which one of several co-owners may be "advertised out", for a failure to contribute his proportion of the required expenditures.

ARTICLE 'E' OF SECTION 6 deals with the period during which annual assessment work is required to be done, and establishes the fiscal instead of the calendar year therefor.

Should the proposed bill be enacted, Articles 'B', 'C', 'D', and 'E' of Section 6 should become a part of it. In other words, they should stand or fall with the bill. And as shown in the concluding part of this report, we think the bill as a whole should fail of passage; since except for one or two matters there suggested, there is no necessity for changing the present mining code.

SECTION 7, while necessarily recognizing existing extra-lateral rights, repeals the 'apex' law as to all claims which may be located after the effective date of the proposed bill. By this Section the holder or patentee of a mining claim obtains the exclusive right of possession and enjoyment of the surface and minerals which lie beneath the claim and within vertical planes passing through the surface boundaries, but is denied the right to follow any mineral deposit beyond such planes.

We believe that in repealing the 'apex' law, a provision should be made to offset the situation that otherwise would result in the case of a comparatively flat vein dipping into the earth at a slight angle. With extra-lateral rights abolished, a claim 600 ft. in width by 1500 ft. in length, as authorized under the present law, located along the strike of such a vein, would give the locator only 300 ft. of the vein on its dip, assuming he had located so that the outcrop passed the centre of his end-lines. This small segment of the vein would not justify development expenditures. We therefore think that under such circum-

stances the locator should be authorized to locate a claim in the shape of a square 1500 ft. by 1500 ft.

With the exception above noted, we are of the opinion that the 'apex' law, with all its baleful incidents, should go; and we also are of the opinion that the language of Section 7 is appropriate and legally sufficient to accomplish the end sought.

SECTIONS 8, 9, 10, 11, AND 12 relate to the procedure to be followed in connection with the acquisition of patent and include such questions as adverse claims against applications for patent, descriptions of claims, surveys, verification of application papers and affidavits, etc.

Should the proposed bill be enacted into law, these sections should become a part of it.

ARTICLE 'A' OF SECTION 13. By this article a mill-site or worksite of not exceeding ten acres of non-adjacent non-mineral land may be acquired by the owner of a mining claim for mining and metallurgical purposes. This provision is very similar to our present mill-site law except for this purpose under this article the applicant is permitted to patent ten instead of five acres. If the Arentz Bill shall be enacted, this article should be incorporated therein.

ARTICLE 'B' OF SECTION 13 provides that where unoccupied land belonging to the public domain, either contiguous or non-contiguous to a mining claim, is needful in large areas for mining and metallurgical purposes, the surface rights of such land may be acquired without limit as to aggregate area, providing the application has been approved by the Secretary of the Interior. Land classified as being capable of irrigation may not be located under the terms of this act. By Article 'C' of this section mineral rights underlying land thus acquired shall be reserved and shall be subject to location and patent.

If the Arentz Bill becomes law, Article 'A' of Section 13 should become a part thereof; but we are not aware of any necessity for the provisions of Article 'B' and 'C' thereof, since it has never come to our attention that "land without limit as to aggregate area" is needful for mining and metallurgical purposes.

SECTION 14. By this section all moneys paid into the Land Office in lieu of annual labor or improvements, and for extension of tenure beyond five years where no discovery has been made, shall be set aside and be known as the "mineral development fund", to be used within the State and as nearly as practicable within the mining district from which payments were made, for the general purpose of developing the mineral resources of the several mining districts.

As previously stated, we believe the development of the land itself is the thing to be desired; and we therefore are of the opinion that, as at present, annual assessment work should be performed on the claim, and that there should be no alternative.

SECTIONS 15 AND 16 are merely re-enactments of Sections 2339 and 2340, Revised Statutes of the United States, dealing with the question of vested rights in the use of water on the public domain for mining and other purposes; and providing that all patents granted shall be

subject to any accrued water-right, or rights to ditches or reservoirs used in connection with such water-rights.

SECTION 17 re-enacts Section 2343 of the Revised Statutes of the United States, which authorizes the President to establish additional land districts whenever he may deem the same necessary for the public convenience.

SECTION 18 relates to land and shoal water between low and mean high tide on the shores, bays, and inlets of Bering Sea, within the jurisdiction of the United States, and declares the same to be subject to exploration and mining for gold and other precious metals, under such reasonable rules and regulations as the miners in organized mining districts may make governing the temporary possession thereof for exploration and mining purposes.

We express no opinion on this subject, leaving its discussion to those who are more intimately interested in the development of these distant lands.

SECTION 19 re-enacts Section 2346 of the Revised Statutes of the United States, which provides that land grants to railroad corporations in aid of railroad construction, shall be so construed as not to embrace mineral lands, which are reserved to the United States.

SECTION 20 re-enacts Section 910 of the Revised Statutes of the United States, relating to possessory actions, and provides that no such action in any court of the United States shall be affected by the fact that the paramount title to the land is in the United States, each such case to be adjudged by the law of possession.

SECTION 21 re-enacts the provision of an act of February 24, 1909 (35 Stat. at large p. 645), relating to the return of excess payments made to cover cost of work performed or to be performed in the offices of the United States Surveyor General.

SECTION 22 provides that where, by special act of Congress, land has been opened to exploration under the mineral-land laws but subject to any special limitation or condition expressed in such special act, the Arentz Bill shall not be construed as waiving such limitation or conditions.

If Congress passes the Arentz Bill this provision is proper and appropriate.

SECTION 23 would make land chiefly valuable for building stone subject to location under the Arentz Bill, instead of under the placer law, which latter law would be superseded by this proposed new legislation.

If the Arentz Bill is enacted, this provision would be proper.

SECTION 21 provides that the provisions of the proposed Bill shall not apply to public lands in the States of Michigan, Wisconsin, Minnesota, Missouri, Kansas, or Alabama. In these States the present Federal Mining Law is not in force. Mining lands there have either been disposed of under special acts of Congress or under the agricultural land laws.

SECTION 25 is the repealing section. It sweeps away our present mining law.

IN CONCLUSION the present mining law has been in operation for a long period of time, during which doubtful provisions thereof have been judicially construed with

the result that now most mining men have a fairly accurate knowledge of what steps must be taken in order to perfect a valid location and obtain title to the lands embraced therein. We are of the opinion that the enactment of a new or revised code of mining law would cause confusion and uncertainty and lead to much litigation. And in this way we believe the good results hoped for by the proponents of the Arentz Bill would be greatly outweighed by the evils suggested above. In other words, by a repeal of the present well understood law we would be surrendering something of great practical value for something whose utility remains to be demonstrated.

In view of the confusion and litigation likely to result from the proposed revision, and also in view of the fact that among practical mining men there seems to be a feeling that with the change of the time for the performance of annual assessment work from the calendar to the fiscal year, and with the elimination of the 'apex' feature, the present law would give results quite satisfactory, we believe it would be better to repeal the present law relating to extra-lateral rights, adopt a provision fixing a more satisfactory mode of marking boundaries, make provision for the recording in the Local Land Office of mining locations, and let it go at that.

ROAD-BUILDING, during the last 20 years, has become one of the largest industries in America. At present it forms the major part of the construction industry. There are now identified with the road industry 80,000 Federal, State, county, township, and city officials, 7000 road-contractors, 2000 bridge-contractors, 1196 manufacturers and dealers in road-building machinery and materials, 7338 firms manufacturing highway transportation equipment, 25,000 civil, highway, and chemical engineers, and 842 national, State, and local highway associations, and engineers' and contractors' organizations. There are 206 firms manufacturing portland cement for road-building, with an annual output of 125,000,000 bbl., valued at \$375,000,000, and total capital of \$366,914,110. The dealers in crushed stone number 380, with an output of 9,700,000 tons for road purposes, annually, that is valued at \$9,500,000. The capital invested in this branch of the industry totals \$27,900,000. Asphalt manufacturers number 42, with an annual production of 1,000,487 tons, valued at \$44,610,000, and total capital of \$126,000,000; 340 firms producing annually 23,000,000 tons of sand and gravel of a total value of \$13,000,000 and having a grand total of invested capital amounting to \$9,130,000 are involved in the road industry. In addition there are 2000 firms manufacturing 300,000 commercial cars, valued at \$400,000,000, and 165,000 tractors, valued at \$225,000,000. In 1919 approximately \$400,000,000 was spent on road-construction in this country; in 1920 about \$600,000,000; and it is estimated that for 1921 approximately \$800,000,000 will have been spent. For next year nearly one and one-half billion dollars is available for road-construction, and it is expected that actual cash expenditures for work of this character will pass the billion-dollar mark.

Concentrating an Ore of Wolfram, Bismuth, and Molybdenite in Australia

By H. W. Bowater

*The old mill erected by the Irvinebank company consisted of 10 stamps, each of 850 lb., a rock-breaker, a Harz jig, two Krupp tables, two Luhrig vanners, three sand-pumps, one mixer, six flotation-cells, and the necessary settlers. Power was supplied from a small colonial-type boiler. The ore was carted to the mill and fed by hand into the rock-breaker; the broken product was elevated into the battery-bins and fed into the mortar-boxes, the pulp passing to a classifier, the underflow from which went to jigs, tables, and vanners, the overflow to settlers. After the removal of a bismuth-wolfram concentrate, the pulp was pumped to the flotation plant, where the molybdenite was recovered. The erection of the first unit of the new mill was started in August 1917, and milling and concentrating began in February 1919. The ore is quartz, in which the rich minerals occur in lumps and patches. Between the quartz and the granite there is a transition zone, through which the molybdenite is evenly distributed. The principal minerals are molybdenite, wolfram, metallic bismuth, bismuth sulphide, bismuth carbonate, and, rarely, a little scheelite. The wolfram is friable; care must be taken to slime it as little as possible, and to crush the molybdenite as much as possible.

MILL. The ore from the mines is delivered by a rope-tram into a bin, passing from this over a grizzly with 2-in. openings. The oversize goes to a jaw-crusher, set to break to $2\frac{1}{2}$ in. and thence to a second grizzly, with $1\frac{1}{2}$ -in. openings, the oversize from which passes to a second crusher, set to break at $1\frac{1}{2}$ in.; it then joins the fine material from the two grizzlies, the whole passing to an intermediate bin. From here the ore is trammed to the battery-bin, side-tipping trucks of 1-ton capacity being used. At present the first unit of 20 stamps is in operation; these are arranged in groups of five to each box. The ore is fed by means of Challenge feeders. The stamps, of 1250 lb., drop from 6 to 7 in. at a frequency of 100 per minute. The depth of overflow is maintained at 10 in. Woven-wire screens are used, with an aperture of 1/10 to 1/12 in., the latter for ore rich in molybdenite. The duty varies from 5.5 to 5.8 tons per stamp per 24 hours.

The mortar-boxes are set on concrete foundations with a $\frac{5}{8}$ -in. rubber sheet between box and concrete. The pulp is automatically sampled before passing to hydraulic classifiers; one classifier is used for each five stamps. The underflow from each classifier passes to a settler, the overflow from all passing to another settler; the overflow from the last is divided and passes to two more settlers. The

underflow from each of the *B* settlers (see flow-sheet) passes to Wilfley and Buss tables, one table being provided for each settler. The overflow from these settlers passes to a large settler, *D*, the underflow of which passes to a Wilfley table. The overflow of settler *D* passes to a still larger settler *E*, the underflow of which is sent to No. 2 Group of hydraulic classifiers.

Three products are made by the concentrating tables: bismuth-wolfram concentrate, middling, and tailing. The concentrate assays 30 to 45% tungsten trioxide, and from 5 to 7% bismuth. The middling assays about 8 to 10% tungsten trioxide, 5% molybdenite, and contains a moderate percentage of pyrite. The tailing contains from 0.1 to 0.13% of tungsten trioxide, the amount of molybdenite varying according to the degree of fineness attained during crushing. The concentrate is sent to the drying and magnetic-separation room; the middling goes to Wheeler pans, thence to hydraulic classifiers, the underflow of which passes to Krupp tables, producing bismuth-wolfram concentrate, middling, and tailing. The concentrate, assaying from 25 to 40% tungsten trioxide, and from 3 to 5% bismuth, is sent to the drying and magnetic-separation room. The middling from the Krupp table is elevated back to the Wilfley table dealing with the underflow from the settler *D*. The overflow from the classifiers passes to a settler *F*, the underflow of which goes to an Isbell vanner, producing a bismuth-wolfram concentrate and a tailing. The concentrate, containing from 15 to 25% tungsten trioxide, and from 3 to 4% bismuth, is sent to the drying and magnetic-separation room. The overflow passes to two settlers *G*. The underflow of this, together with the overflow of the settlers *C* and *C.1*, passes to two classifiers (No. 2 Group), the underflow of which passes to an Isbell vanner, the overflow going to settlers *G*.

The tailing from the Wilfley and Buss tables is passed to two settlers *CB*, the underflow of which is sent to the molybdenite-flotation plant, the overflow being pumped back to the mill-reservoir. The tailing from the Krupp tables and the vanners is passed to a settler *H*, the underflow of which is passed to the molybdenite-flotation plant, the overflow going to the creek dam. The underflow of settler *G* goes to slime-frames, producing a low-grade concentrate and a tailing, the overflow going to the waste settler *L*. The tailing, together with the underflow of settler *H* passes to the molybdenite-flotation plant.

The underflow of settler *K*, together with No. 2 concentrate from the slime-frame is treated on buddles and a Luhrig vanner, producing bismuth-wolfram concentrate, middling, and tailing. The concentrate is sent to the

*Abstracted and condensed from the proceedings of the Aust. I. M. M.

drying and magnetic-separation room; the middling is returned to the vanners, and the tailing is sent to waste.

TREATMENT OF BISMUTH-WOLFRAM CONCENTRATE. The bismuth-wolfram concentrate is dried, sampled, weighed, and assayed; it is then sized into three grades (through 30 mesh, through 16 mesh, and through 12 mesh) and treated magnetically. Any oversize is crushed and re-sized. Two magnetic separators of the Dalbonze bracket type are used, with current at 110 volts. The product from the separators is a clean wolfram concentrate, and a bismuth concentrate containing a little wolfram. A small amount of iron is also obtained, which contains a low percentage of wolfram; this is dressed on a Wilfley table, producing a fairly high-grade wolfram concentrate, which is shipped.

MOLYBDENITE-FLOTATION PLANT. Each unit of the molybdenite-flotation plant consists of two sub-units (see Fig. 2); No. 1 deals with the tailing from the Wilfley and Buss tables, and No. 2 deals with the tailing from the Krupp tables, from the Isbell vanners, and from the slime-frames. The underflow from settlers (CB) (see Fig. 1) is passed to settlers of the cone type. The dewatered pulp is passed to a mixer, where the necessary oil is added. From the mixer the pulp is fed to distributors. The flotation-cell is of the cone type, 4 ft. 9 in. diam., and 3 ft. 3 in. deep. The distributor occupies 1 ft. 11 in. of the centre of the cell, leaving 1 ft. 5 in. of the outer diameter as the flotation area. The underflow of the No. 1 flotation-cells passes to distributors on the No. 2 cells, the concentrate going to a dewaterer. The underflow of No. 2 cells is sent to two large settlers, the liquor overflowing to the storage reservoir, and the tailing passing to waste, the overflow combining to provide the water necessary for flushing the pulp.

The concentrate from the No. 2 flotation-cells combines with that produced in the No. 1 cells and passes to a dewaterer. The overflow from the two cone-settlers is passed to a large settler *J*, the underflow of which is sent to No. 2 sub-unit, the overflow passing to a still larger settler *K*. This precaution is taken to prevent trouble in case of the overflow of the two cone-settlers, and to obtain a better settlement of the fine material.

The tailing from the Krupp tables, from the Isbell vanners, and from the slime-frames, and the underflow from settler *J* are all sent to a large settler *L*. The underflow from this is passed to two cone-settlers, the overflow going to waste. The dewatered pulp from the cone-settlers is then dealt with as in the No. 1 Sub-unit, the feed from the mixer passing to a set of three flotation-cells, the concentrate going to the dewaterer.

The molybdenite dewaterer is a rectangular box, 3 ft. long by 2 ft. wide and 6 in. deep. On the bottom of the box is an 80 mesh screen. The pulp is delivered to the

box, the latter being given a shaking movement. The dewatered concentrate is removed periodically from above the screen, the liquor and the fine molybdenite passing through the screen into a large 3-compartment box. The fine material settles in this box, the liquor overflowing to the storage-reservoir. The fine molybdenite in the first compartment of the box is removed periodically and dressed, to a marketable concentrate, in keeves. The product from the second and third compartments, together with the skimmings from the keeves, are returned to the mixers. As much as possible of the liquor is saved and pumped from the storage reservoir to tanks that are

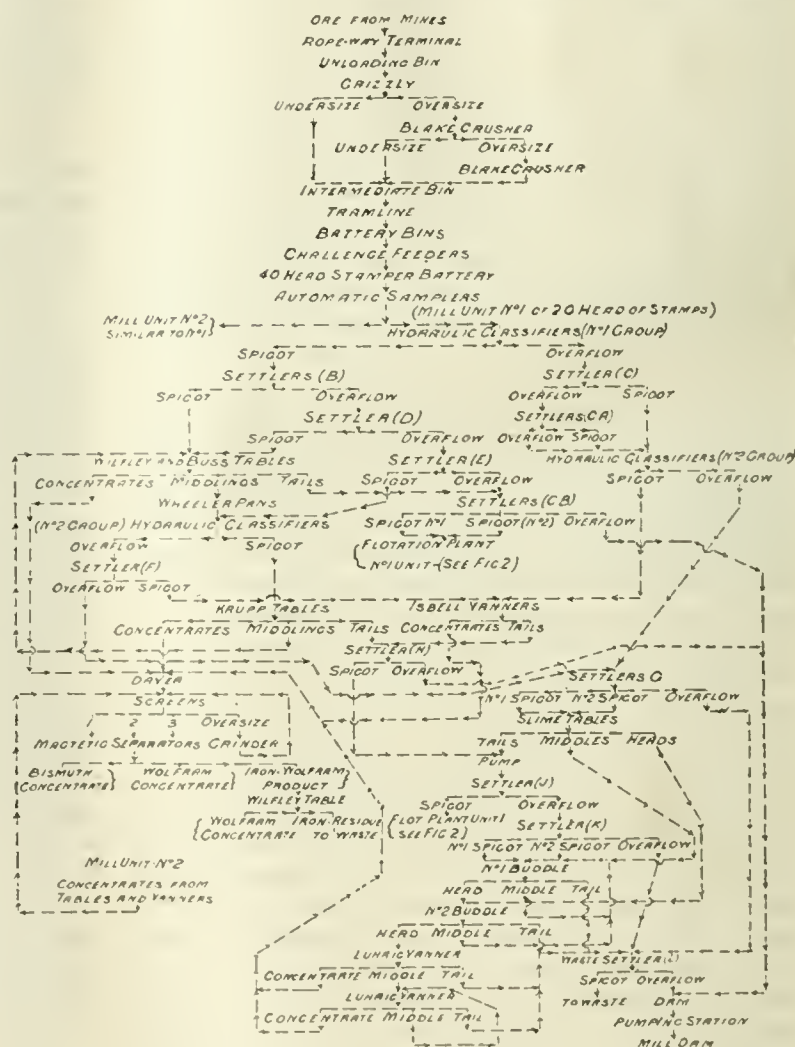

FIG. 1. FLOW-SHEET

placed above the mixers, thus providing liquor for the mixers and sufficient overflow for the flotation-cells. The dewatered molybdenite concentrate is dried and is then ready for the market. That obtained from above the screen assays from 85 to 94% molybdenite. The dressed concentrate from the first compartment of the box assays from 80 to 85% molybdenite, the purity depending on the cleanliness of the water used in flotation and the nature of the ore.

LABORATORY CONTROL. Mine- and battery-samples are assayed for tungsten, molybdenum, and bismuth, as is an average check sample that is weighed from the daily

pulp-samples, in amount proportioned to the tonnage crushed. The bismuth-wolfram concentrate from the Willey and Krupp tables and the vanuers is assayed for tungstic acid and bismuth. The molybdenite concentrate is assayed for molybdenite, with a check for insoluble. Separated wolfram or bismuth concentrate is assayed for tungsten and bismuth; the acid method is used on all samples analyzed for tungstic acid; mine- and battery-samples are analyzed colorimetrically for both molybdenite and bismuth. The bismuth in the concentrate is determined by gravimetric methods, using the acid solution from the tungsten test. Occasionally a gravimetric test is made for molybdenum and bismuth in the mine- and battery-samples.

The following methods are used in the chemical laboratory:

METHOD OF ESTIMATION OF TUNGSTEN TRIOXIDE IN CONCENTRATES AND ORES. It is most important that the ore be finely ground. Treat 0.5 gramme of the concentrate with 60 cc. of hydrochloric acid, having the beaker covered with a watch-glass. Digest for from 2½ to 3 hours, with further additions of acid as the solution evaporates. Add 25 cc. of concentrated nitric acid, and evaporate to about 10 cc. It is best not to heat to dryness, as there is danger of overheating the residue and causing the tungstic acid to become insoluble in ammonia. Take up the residue with 50 cc. of hot water and allow to stand for 3 hours. Filter and wash well with hot water. The residue in the beaker is now treated with about 50 cc. of ammonium hydrate (1 to 1), to which 1 cc. of strong hydrochloric acid has been added. The solution is filtered, then transferred to a weighed porcelain dish and evaporated to dryness. The dish is then heated (gently at first) to expel ammonium salts, and the residue is weighed as tungsten trioxide.

COLORIMETRIC ESTIMATION OF BISMUTH. Weigh 0.05 gm. of finely ground ore for 3% bismuth or over, or 0.5 gm. for ores containing under 3%; transfer to a 500-cc. graduated flask, add 25 cc. nitric acid, and 75 cc. water, and boil for 10 minutes; cool, fill up to the mark with water, mix thoroughly, and filter about 100 cc. into a dry flask. Fill a burette with the solution, which is now ready to compare with the standard solution of bismuth. Fill a similar burette with standard bismuth solution, add exactly 1 cc. to a 50-cc. Nessler tube, together with 10 cc. of a 10% solution of potassium iodide, and three drops of sulphurous acid. To a second Nessler tube add 10 cc. of potassium iodide solution and three drops of sulphurous acid, and then add the sample until approximately the same depth of yellow is obtained in the standard tube; then read the burette. If the reading were 5 cc., and if 0.5 gm. of ore had been taken, the result would be 10% bismuth.

To prepare the standard bismuth solution, weigh 0.025 gm. of pure metallic bismuth; transfer to a 500-cc. graduated flask, add 25 cc. of nitric acid and 75 cc. of water. Boil gently for 10 minutes, cool, make up to the mark with water and mix; 1 cc. of this solution equals 0.00005 gm. of bismuth. In calculating, divide the 500 cc. by the

number of cubic centimetres consumed of the sample, and multiply by the value of 1 cc. of the standard; this multiplied by 2000 will give the percentage.

COLORIMETRIC ESTIMATION OF MOLYBDENITE. Weigh 1 gm. of the finely ground ore and treat with aqua regia. The solution is evaporated repeatedly to small bulk with nitric acid, and then evaporated to a pasty consistence. Add 30 cc. water and 10 cc. hydrochloric acid, warm, stir until clear; add 15 cc. of ammonium hydrate and boil for a few minutes; filter into a 250-cc. flask, wash the precipitate on the filter with hot water, make the solution just acid with acetic acid, then add 10 cc. strong acetic acid in excess; cool, make up to the mark, and mix. The solution is now ready for comparison with a standard ammonium molybdate solution.

The standard ammonium molybdate solution is made by adding 2 cc. of ordinary molybdate solution, as used

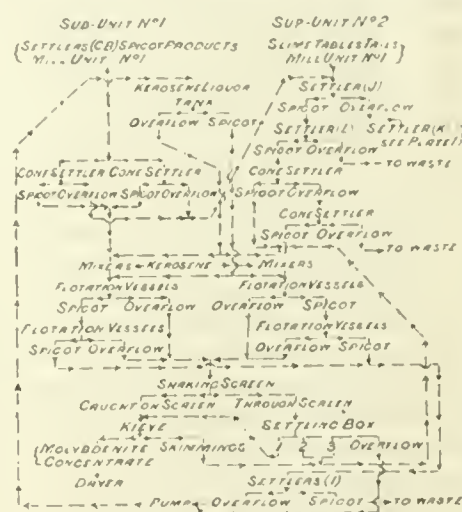

FIG. 2. FLOW-SHEET OF MOLYBDENITE-FLOTATION UNIT

for estimating lead (9 gm. per litre), to a 250-cc. graduated flask; add 20 cc. of hydrochloric acid, 30 cc. of ammonium hydrate, and boil for a few minutes, to obtain approximately the same conditions as in the sample. Make just acid with acetic acid, and add 10 cc. in excess; cool, make up to the mark, and mix. Make up a fresh solution of tannic acid, 0.5 gm. to 100 cc., and fill a burette with the standard solution, a second with the sample, a third with the tannic acid; add 2 cc. of standard solution and 2 cc. of tannic solution to a 50-cc. Nessler tube; dilute to the mark, and mix gently. To a second Nessler tube add 2 cc. of tannic acid, then add the sample solution until the same color is obtained. The value of the standard molybdate solution is calculated as follows: The ordinary solution is usually standardized against 0.3 gm. lead sulphate, which consumed, say, 20 cc. of it; 0.3 gm. lead sulphate is equal to 0.1584 gm. molybdenite; therefore, 2 cc. is equal to 0.01584 gm. molybdenite. This is the total value of the 250 cc. kept as the standard; 0.01584 divided by 125 gives the value of 2 cc., the amount used in the Nessler tube for comparison, that is, 0.0001267 gm. molybdenite. Thus if 8 cc. of the sample prepared from 1 gm. ore were consumed, the result would be 0.39%

molybdenite; 2 cc. is chosen as giving a convenient color, and maintained as far as possible for convenience in memorizing. This method is the one suggested by G. Spurge and has been found to give good results with low-grade ore, battery-pulp, and tailing.

ESTIMATION OF BISMUTH IN BISMUTH-WOLFRAM CONCENTRATE. The wolfram is estimated as previously shown. The filtrate, after filtering the tungsten trioxide, is evaporated to small bulk, and the nitric acid is expelled by the addition of hydrochloric acid and by boiling. Owing to the absence of lead in the concentrate, no sulphuric acid is required to convert this into lead sulphate. Dilute the solutions and saturate with sulphuretted hydrogen. Bismuth, together with arsenic, antimony, molybdenum, and other metals, is precipitated as the sulphide. Filter and wash thoroughly with hot water. A hot solution of potassium cyanide is then passed through the precipitate, when the impurities are dissolved, leaving the bismuth sulphide undissolved. Wash with hot water, dissolve in nitric acid (1 to 1), dilute a little, and boil. Partly neutralize the solution, but without producing any permanent precipitate, and then add a solution of ammonium carbonate in slight excess. Allow the solution to stand on the hot plate for some time and until the bismuth carbonate has settled. Filter and wash with hot water; dry the precipitate and ignite in a weighed porcelain crucible, first removing the precipitate from the filter-paper, which is burned to an ash, then add the precipitate. Ignite at a low red heat, cool, and weigh as bismuth trioxide (Bi_2O_3).

VOLUMETRIC ESTIMATION OF MOLYBDENITE. One gramme of the ore is weighed and treated with nitric acid and a little hydrochloric acid, the molybdenite being converted into molybdic acid. The solution is evaporated repeatedly to small bulk with nitric acid, and then evaporated to a pasty consistence. The residue is extracted with ammonium hydrate, the solution is boiled, then filtered, the residue being washed with hot water. The solution is made up to 250 cc., and mixed thoroughly; 20 cc. standard lead sulphate solution (measured from a burette) is acidified with acetic acid, diluted to 100 cc., and boiled. This solution is then titrated with the assay solution until a faint yellow tinge is obtained, using tannic acid solution as indicator. On the basis of 1 gm. taken, the reading obtained less 0.2 cc. divided by 1978.75 gives the percentage of molybdenite. The standard lead sulphate is prepared by weighing 7.5 gm. of pure dry lead sulphate; take up with 400 cc. of ammonium acetate (slightly acid with acetic acid), and dilute to 1 litre. When dealing with rich molybdenite concentrate take 40 cc. of lead sulphate solution instead of 20 cc.; note reading, deduct 0.2 cc., and divide by 2 before dividing into 1978.75. The filter-paper containing the insoluble can be dried, ignited, and weighed as a rough check against the figures, the addition of percentage of insoluble and molybdenite giving about 99%.

THE production of zinc in France has decreased 80% since 1913, largely because of the high cost of coal used for smelting.

Vanadium

*Del Rio, in 1801, discovered vanadium in ore from Mexico, and named it erythronium; but later, when his conclusions were attacked by others, he became doubtful of his own work, and decided that erythronium was merely impure chromium. Sefstrom, in 1930, while examining a piece of peculiarly soft iron smelted from the Taberg iron ores, suspected the presence of a new element, and believed that the slag from the smelting of these ores should contain it. From this slag he succeeded in isolating the new element which was named after Vanadis, a surname of the Scandinavian goddess Freya. The principal vanadium minerals mined as ores of this metal are patronite, rosecoelite, vanadinite, and carnotite.

According to Emmons, several water-soluble compounds of vanadium are known to occur in nature, and the metal could have been transported in the form of any of them. Vanadium was at one time considered a rare element, but it has been found to be widely distributed. In spite of this fact, deposits of vanadium sufficiently rich to be of commercial value are not common. The metal has been found in several European iron ores, in the Permian beds of Germany and Russia, and in the copper deposits of Russia and of Cheshire, England. The last mentioned deposit was at one time of exploitable value. The bauxite deposits of France also contain vanadium.

Patronite is known to have been found in commercially important amounts only in the Minasragra district in Peru. There, according to Hewett, the mineral is found in red shales that have been cut, at the point where the ore-body occurs, by a quartz-porphry dike. At least four distinctly different dike systems exist in the vicinity. The principal deposit has a lenticular form, and its maximum width and length are 28 and 350 ft. It occupies a fault that has displaced the quartz porphyry. It consists principally of (1) a lustrous black hydrocarbon called quisquite, (2) a dull, porous, coke-like mass that is nearly pure carbon, and (3) patronite. It appears that after the quisquite and coke-like material were solidified in the fault-fissure, further movement sheared and crushed them and the enclosing shales, and that then the patronite filled and solidified in the cavities thus formed or previously existing in the carbonaceous mass. Veinlets of quisquite and patronite have also invaded the country rock, and the latter has in some places, especially along the hanging wall, been impregnated to saturation with patronite. At the surface the patronite has been altered to red and yellow oxides of vanadium and a green iron vanadate which almost entirely replace or fill cracks and fissures in the shale. Nickeliferous pyrite and other impurities exist in the main lode which contains about 10% of vanadic oxide, whereas the roasted ore averages between 35 and 40% of this oxide. An impregnated, hard, blue-black shale on the foot-wall carries 13% vanadic oxide.

*Abstracted from bulletin No. 115, University of Arizona, by M. A. Allen and G. M. Butler.

Progress in Cutting and Welding With Acetylene

*During the past two years there has been much progress in welding and cutting by means of acetylene. Although in most cases improvements have not been radical, they have been of such a nature as to make the apparatus more reliable and successful in operation, which has resulted in the process becoming safer and more economical. The theory of the operation of torches has become better understood, with the result that back-firing has decreased, lessening one of the annoyances in the operation of the equipment.

There has been a general increase in the application of the processes. Not the least notable accomplishment was that of the manufacturers of welding-gases, who maintained prices during and after the War at little above pre-war figures. This has enabled gas-welding to compete in many cases with electric welding where otherwise, on account of low cost, the latter might have been used. While there has not been any special increase in the size of pieces welded, there has been an increase in the number of such pieces, due to the better education of those doing the work, and to the demonstrated success of large and difficult jobs previously done. Acetylene-welding is coming to be recognized as a safe method of construction and repair when in the hands of good designers and skilled workmen. There has been much discussion of welding large storage-tanks for oil and sundry vessels subject to pressure. Designs have been prepared for storage-tanks having a capacity of 5000 bbl., while somewhat smaller ones actually have been constructed and have proved their worth in service.

A 'Code' has been prepared for regulating the construction of pressure-vessels by a conference committee on which your Association was represented. This Code has been presented to the Boiler-Code Committee of the American Society of Mechanical Engineers for their consideration, and in due time it will doubtless be a strong factor in the production of safe welded pressure-vessels. This is probably the most important development that has taken place during the last two years.

The welding of pipe-lines has been extended greatly, as it has been found that welded joints are more reliable than any other joint, and probably cheaper than any other satisfactory joint for permanent construction. In one instance an eight-inch pipe-line under heavy pressure, was tested at 1000-lb. pressure, hydrostatically, and the welds were hammered with a sledge at that pressure. This test has been found successful in detecting defective welds. The method is not new in some other fields, as for instance in the testing of cast-iron and lap-welded pipe, but its application to welded construction generally is recent. Apparently it is just as effective as in tests for the older methods of joining.

Study of the problem of welding alloy-steel indicates that metal of almost any desired composition can be deposited with the oxy-acetylene torch, but that there are many important problems like pre-heating, heat-treatment, and annealing to be considered. Duroiron, which is a high-silicon cast-iron, is being successfully welded, but must be most carefully pre-heated. Manganese-steel is difficult to work, but good results are being obtained on simple castings. The welding of alloy-steels which are used where great strength is required, does not offer much promise, unless the metal can be poured and heat-treated. Nickel-steel, chromium-steel, and vanadium-steel are splendidly welded, but as welds are almost always made where great strength of metal is needed at a point of maximum stress, further research in this direction is of importance. Monel metal has been welded satisfactorily for making containers for acid. Monel metal is also used for valves and other specialty work, and welding is being studied in this connection.

Oxy-acetylene welding is considered by many users of all forms of welding, to be better in quality than electric-arc welding. Where especially high-quality welding is required and severe tests are to be passed, oxy-acetylene welding is being used almost to the exclusion of the electric process. When welding by the oxy-acetylene process a single butt-weld is considered the best practice; if properly made such a weld will give complete satisfaction for any gauge of metal from the lightest to more than an inch in thickness. Latest practice in electric-arc welding advises a lap-joint, thus making two welds; or the covering of a butt-weld by a double lap-welded strap. This latter practice is undoubtedly based on the lack of ductility of electric-arc welds, and means are, therefore, taken to keep the stress off the essential butt-welds. This means three electric welds to one by oxy-acetylene, besides entailing the use of extra material.

Oxy-acetylene cutting has been in severe competition with cutting by oxygen used with various fuel-gases. It has been determined that a large part of this competition has been due to the difficulties of obtaining compressed acetylene during the War and immediately afterward. The efficiency of acetylene for this work is being more and more recognized. Heavy cutting is a field where the process has been limited by the inability of equipment to supply sufficient oxygen. Some interesting heavy cutting has been done by using special knowledge of the need for oxygen. In one case 27 ft. of 15-in. steel was cut in removing the hollow circular riser of an enormous casting. Two regulators were connected on the reduced-pressure side, and the oxygen was led through a large hose to the torch. At the Philadelphia Navy Yard, five regulators were connected to a common low-pressure pipe, 2 in. diameter; an air-hose was used to carry the oxygen to the blowpipe, which had a specially large tip. The oxygen-bore was $\frac{1}{4}$ in. diameter. By this means and by

*Report of the Oxy-Acetylene Welding Committee at the annual convention of the International Acetylene Association in New York in October 1921.

increasing the oxy-acetylene pre-heat a little, beautiful cuts 24 by 24 in. were made. Oxy-acetylene cutting has been much used for constructive work during the past two years. Forgings have been trimmed practically to dimension, and in some cases cutting has been so developed that intricate shapes such as connecting-rods are being cut out with the oxy-acetylene torch.

Cutting cast-iron is an extremely interesting development of the past several years. The fundamentals of the process seem to be that a large excess of pre-heat must be used, so that the cast-iron is heated to a red temperature over a considerable space. A large and powerful oxygen-jet is then directed on the red-hot cast-iron, with the heavy pre-heat still applied. The kerf made in the iron casting is quite similar to that made in the cutting of steel, except that the width of the kerf is generally double that in a steel casting of similar size, and is not quite so clean looking. It is easy to see that more gases are used than in similar steel cutting, and it has been noted in tests that the time for cutting is about double that for steel; therefore, cast-iron cutting is three or four times as costly as steel cutting, and in most work it can hardly be said to compete with saws. There are, however, many places where heavy chamfer cutting is to be undertaken and a couple of welders are standing by. Normally the cast-iron would be 'V'd' out by a laborer with compressed-air driven tools, and probably a day or two would be required for preparing a large job. Although cutting by torch is more expensive than is the actual preparing of the work by compressed-air tools, it is certainly economical in the above case, when we consider that two operators must stand by, thereby accumulating an expense of \$10 to \$15 per day each.

An interesting and valuable use of oxygen is the burning of holes into salamanders in blast-furnaces, to permit the insertion of the dynamite used in breaking them up. A similar process is used in opening furnace tap-holes. This is done by heating the point at which the hole is desired to a red heat and directing against it a steel pipe, through which oxygen is passed under a heavy pressure, often up to 250 lb. The burning of the steel pipe brings the cast-iron to a temperature for the oxygen to combine with it. Of course, the steel pipe is gradually burned away; but the hole may be made of almost any depth by supplying sufficient pipe and oxygen.

Oxygen manifold and pipe-line installations have been recommended together with the use of cylinder platforms. The use of platforms enables cylinders to be unloaded from trucks and re-loaded without a large crew of laborers being called. Simplifying the problems of handling cylinders helps to stabilize the industry by removing an annoyance. In large installations for welding and cutting, such as are found at some of the steel-mills, improved means of handling oxy-acetylene tanks and carbide have been introduced, and safety rules provided for their storage and handling. These improvements and rules not only have resulted in rendering the process more economical, but they have decreased accidents. Safety rules should be advocated by all interested in the

acetylene process and their adoption should be urged upon all users regardless of the size of their work. One of the interesting developments is the use of automatic machines for welding tubing from strip steel, the product being equal to seamless tubing and costing much less.

The problems confronting our industry are many and varied. It is gradually being discovered that welders cannot be made in six weeks, except for the simplest operations; and, while there is not yet complete agreement as to the best methods for training welders, ideas are being gradually crystallized and the condition will improve rapidly as soon as those vitally interested appreciate the need of proper and thorough training, not only in the actual handling of the apparatus, but in the fundamental principles involved. When this time comes, welders will be selected intelligently instead of haphazardly, as is too often done at present. Your committee urges on the members who are interested that they give this phase of our problems special attention.

During the last two years considerable progress has been made in the study of the fundamental problems of gas-welding, such as the best quality of welding-wire, the necessity for satisfactory quality of steel plate for welding, and other problems which are strictly research matters. Such problems cannot be solved in a short time. There are many factors involved, not the least of which is the necessity of proving to those who make the wire and plate that their product must be of satisfactory quality aside from its chemical composition, if good welding is to be secured. Already progress has been made in this direction, but much remains to be done. Your committee hopes that active co-operation of the members may be secured in furthering these important matters.

Research on the proper composition of welding-wire seems to show that ordinary straight carbon-steel is not the best metal for the purpose, but that alloy-steel of the proper composition should be used if the best results are to be obtained. This is important and the subject requires a large amount of experimenting, but there is no question that better results may be expected within a reasonable time.

The superiority of brass pipe is conceded by plumbers on account of the endurance and resistance to corrosion. There are innumerable instances on record where iron pipes after three or four years service have been found so filled with rust that an ordinary lead-pencil could not be passed through them. This rusting, which seems inevitable in iron pipe, will cause leaks not only in the joints where the thread has decreased the thickness of the metal, but at other points of structural weakness. Brass pipe has occasionally failed from 'season cracking'. This defect is due to initial strains in the metal, a condition now understood by manufacturers, and can be eliminated by a suitable relief anneal. In concealed piping, where costs of repairs are necessarily heavy on account of tearing out walls and floors, iron pipe should never be installed.

REVIEW OF MINING

\$60,000 ROBBERY AT THE ARGONAUT MINE IN CALIFORNIA

Six men armed with sawed-off shotguns blew open the safe of the Argonaut mine at Jackson, California, early on the morning of December 1, and escaped with more than \$60,000 in gold amalgam in two automobiles driven by two others who had acted as lookouts during the robbery.

George W. Lucot, sheriff, was on the road about an hour afterward with a posse, searching in the direction of Cone, following a report that the robbers had headed out of the Mother Lode into the San Joaquin valley. The loot was a month's clean-up for the mine. Its weight was 455 lb., and the robbers apparently were aware of the fact that the mine's plates had just been scraped preparatory to melting down bullion for shipment. The amalgam was in the form of balls.

The two millmen on duty, Reese Williams and James Podesta, were overpowered and bound with ropes, but Williams managed to back up against an emery wheel afterward and rubbed the rope in two. He then released Podesta, but they found the bandits had cut the telephone wires at the mine and so they were delayed in giving the alarm. Red bandana masks were worn by the men, whom the millmen said were well dressed and apparently familiar with the mine's operations. The mine is owned by the Argonaut Consolidated Mining Co., of which John T. Smith of New York is president.

FEDERAL TAXATION OF MINES

The revised tax bill as approved by the President on November 23 provides that all gold-mining companies be exempted from the excess-profits tax for 1917, whether they have paid the tax or not, and in the cases of those companies which have paid the tax the same will be refunded. The existing law relating to depletion allowance in the case of mines, oil and gas wells, and timber is continued, but the depletion allowance based on discovery shall not exceed the net income from property upon which the discovery is made except where such net income is less than the depletion allowance based on cost or fair market value as of March 1, 1913. The war-profits and excess-profits taxes are repealed, effective January 1, next, and the maximum surtax rate is fixed at 50%.

RUMOR OF CONSOLIDATION OF MICHIGAN COPPER MINES IS DISCREDITED

Nothing is known at Houghton of the report, emanating from Duluth and published in newspapers, to the effect that "most of the big copper mining companies operating in the Lake Superior district will be consolidated some time next year with the Calumet & Hecla Mining Co. as a nucleus". Local mining men state they are without knowledge of any project of that kind. It is pointed out in the Duluth report that "operating costs of mines in the Lake country are so high compared with companies mining 'disseminated' ore in other sections of the country that it is important that they be brought down to much lower levels. In addition to high material prices and labor, greater depths of the mines and decreasing grade of ore have increased costs. Great economies, it is added, could be had by centralization".

There is not so much to this argument as might appear on the face of it, mining authorities there point out. The only big properties not now in control of Calumet & Hecla are the Copper Range, Quincy, and the Stanton mines. It is not believed that a consolidation including these properties would work for lower costs, inasmuch as they apparently have costs down to the minimum. All are well equipped and each has effected great economy in operation. Labor costs vary but little and one company buys fuel and materials as cheaply as another. In mining, milling, and smelter practice the most modern methods are employed and the problem of costs has been attacked in every possible direction. This generalization will be found to be true upon analysis. Those who should know merely dismiss the reported consolidation as something without foundation in fact.

U. V. X. APPEALS FROM DECISION IN SMELTER-SMOKE SUIT

The United Verde Extension Copper Co. has appealed to the Arizona Supreme Court at Phoenix from a judgment against it of \$1 and costs secured in Yavapai county by two Verde Valley farmers, David H. Bliss and S. P. Wells, who said they had been injured by the fumes of defendant's smelter to the extent of \$2557. The costs of the case amount to \$1620.

CALIFORNIA MINING BUREAU ISSUES ITS ANNUAL REPORT

The California State Mining Bureau announces the issuance of its Seventeenth Annual Report. In spite of the depression and inactivity of some branches of the industry, the annual value of more than 50 mineral products of California shows a production of a quarter of a billion dollars. The Report is attractively bound in cloth, comprising 600 pages; it may be secured by addressing the State Mining Bureau, Ferry Building, San Francisco, or any of the district offices of the State Mining Bureau. The price of the publication is \$1.75, including delivery charges.

TONOPAH EXTENSION COMPANY BUYS CASH BOY MINE

The Tonopah Extension Mining Co. of Tonopah announced at Tonopah on December 2 that it had purchased the Cash Boy mine from the Tonopah Cash Boy Mining Co. paying for it 100,000 shares of Tonopah Extension stock which is equivalent to \$145,000 based on the market value of Extension stock.

The transaction is one of the most important consummated for some time as it ends litigation involving extralateral rights that would probably have extended over an indefinite period. About three months ago the Extension company brought suit against the Cash Boy for \$15,000 damages, asserting that it held the apex to ore which the Cash Boy was mining. C. E. Stoneham of New York City is the principal stockholder of the Cash Boy. George B. Thatcher and E. H. Mead, both of Reno, are also heavy stockholders. The Cash Boy was capitalized for 2,000,000 shares and on this basis the Extension gave one share of its stock for 20 shares of the Cash Boy. During the past few

weeks it is reported some exceptionally good ore has been opened in the Cash Boy and it is understood that this showing led to the deal with the Extension through which costly litigation was avoided.

REVISION OF THE MINING LAW

The following resolution has been unanimously passed by the Montana Mining Association:

Whereas, for more than a half century under our present laws the mining industry of this country has developed to its present magnitude, and through physical practice and interpretative court decisions and departmental rulings, our people have become familiar with the laws now governing mining, and,

Whereas, the proposed revisions of the present mining laws contain changes so drastic that they will seriously disturb, retard, and injure mining by reason of such proposed changes, therefore, be it

Resolved, That the Montana Mining Association protests against the passage of this proposed legislation; that its passage will work a great hardship upon the mining industry of Montana, with no resultant benefits whatever, and we respectfully recommend to the Congress that it adopt a "hands-off" policy as affecting the laws governing mining.

Resolved, That a copy of these resolutions be sent to our Senators and Representatives, to the press of the State, and to other mining associations.

The undersigned certify that the foregoing is a correct copy.

C. S. MUFFLY, President.
LEO FAUST, Secretary.

PROVISIONS OF THE NEW ACT ON WAR MINERALS RELIEF

The provisions of the new Act passed on November 23 by Congress are in the form of an amendment to the Act of March 2, 1919. They follow: "That all claimants who, in response to any personal, written, or published request, demand, solicitation, or appeal from any of the Government agencies mentioned in said Act, in good faith expended money in producing or preparing to produce any of the ores or minerals named therein and have heretofore mailed or filed their claims or notice in writing thereof within the time and in the manner prescribed by said Act, if the proof in support of said claims clearly shows them to be based upon action taken in response to such request, demand, solicitation or appeal, shall be reimbursed such net losses as they may have incurred and are in justice and equity entitled to from the appropriation in said Act. If in claims passed upon under said Act awards have been denied or made on rulings contrary to the provisions of this amendment, or through miscalculation, the Secretary of the Interior may award proper amounts or additional amounts".

LABORATORY FOR OIL-SHALE INVESTIGATIONS IS IMPROVED

The U. S. Bureau of Mines announces that the oil-shale laboratory at Boulder, Colorado, has been enlarged and equipment added preparatory to more extensive work on Colorado shales. Important changes have been made in the temperature-measuring apparatus and in the drive-mechanism of the horizontal retort. A new position for the pyrometer in the retort-furnace has been selected. They are expected to indicate more accurately the temperature of the shale in the retort and also make possible more definite control of retorting conditions. During the past two years several attempts have been made without success to classify oil-shales by chemical determinations. It has been suggested that the quality of oil to be obtained from a given shale will be most influenced by the C:H:O ratio in the organic matter. Work is under way seeking to determine

this ratio for representative shales. The work involves separation of the organic from the inorganic constituents; elementary combustion analysis of the recovered organic matter; retorting of a sample of the same shale in the assay retorts; and a distillation analysis and chemical examination of the oils produced by the assay-retorts. The work is well under way, although at the start dillently was experienced in making a clean separation between the organic and inorganic parts of the shale. A method for the separation has been developed, however, that appears satisfactory. Experiments in refining oils produced from Colorado oil-shales have been started.

ARIZONA

Bisbee.—With the payment on December 19 to shareholders of record December 2 of a dividend of 50c. per share, Calumet & Arizona will have disbursed \$2 per share this year. It has been able to do this because of the fact that it held something in reserve in its treasury during the 'fat years' when liberal disbursements were made, but which were not quite satisfactory to many of the shareholders at that time. The wisdom of a conservative policy during that period has since been well demonstrated, in the opinion of George A. Newett, one of the directors. The dividends of the present year have not been made from this year's earnings, as is well understood, as no copper has been made since last spring when the company's smelter was shut-down. Several hundred men have been on the payroll since that time, however, this for the main purpose of aiding labor in this trying time. The company has been conducting important development work, repair of shafts and machinery, and will have the property in fine condition when a resumption of mining and smelting is ordered.

Kingman.—A jury verdict of \$20,000 has been given in favor of the Wallapai Mining & Development Co. in its suit against the United States Smelting, Refining & Mining Co. et al. The plaintiff was represented by Frank Pierce of Los Angeles and C. W. Herndon of Kingman. Appeal will be taken to the State Supreme Court. The issue was the disposition of an old mill on ground of the Tennessee mine, which had been under lease to the defendant interests. It was not used, the ore mined having been shipped to the smelting company's works at Needles.—The C. O. D. property, which had been closed after resignation of M. B. Dudley as manager, has been started again under charge of Arthur D. Storke. Development work is being continued and there is expectation that milling will be resumed some time in January.—On the 250-ft. level of the Tuckahoe at Chloride has been cut an 8-ft. vein that is said to sample 300 oz. silver. The find is considered one of the most notable ever made in the district. For years the mine has been worked by the lease method and the ore sent to smelters.—Expensive pumping equipment has been installed at the Kaaba mine, where exploration is being made of an 8-ft. vein of rich gold ore. Diamond-drilling is being performed from the 310-ft. level. The property has its own mill.

Miami.—The Inspiration company is using three shifts in exploration of ground at the old No. 2 Live Oak shaft and is tunnelling at the No. 1 Live Oak. A shaft is being sunk just below the old Porphyry shaft. No ore production is contemplated and the concentrator will remain idle for the present. The company has made the second payment on its \$1,000,000 purchase of the Porphyry claims, remitting \$250,000 on the principal sum and \$22,500 interest.

The resumption recently of copper pouring at the International smelter has had formal celebration at a banquet in the Miami Y. M. C. A., arranged by the Miami Rotary Club, the Globe Luncheon Club, and the Miami Boosters' Club. The furnaces had been inactive for seven months. Now employed at the smelter are about 200 men, all of

them former employees, while 300 more are working in the Inspiration mines and offices, on lately commenced activities. These additions to the employed workers have given the camp a relative degree of prosperity.

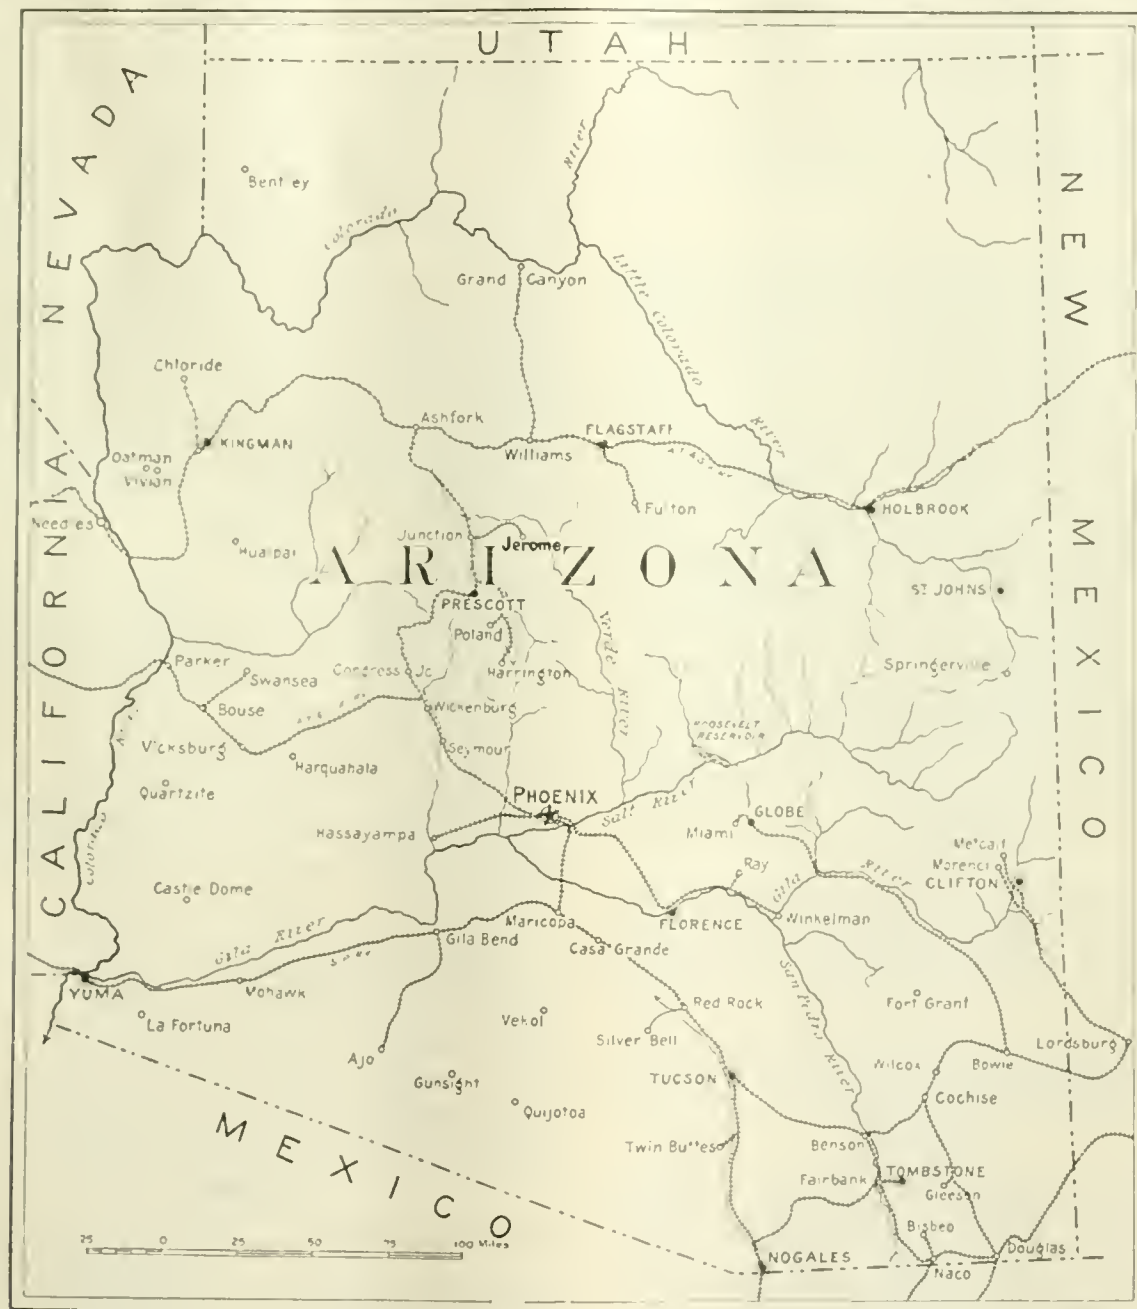

Tucson.—Operations have been resumed at the Yellow Bird mine in the Papago district, 30 miles south-east of here. It will be operated by a company organized by S. W. Purcell of this city. Operation of the Silver Lillie group, 12 miles west of here, under Fred H. Perkins, a mining en-

gineer, plans are made for a leaching- and furnace plant from which a clinker product is to be shipped to Los Angeles for manufacturing uses.

CALIFORNIA

Downeyville.—Definite plans have been made for the reopening of the Oro, the Oxford, the Big Boulder, and the Finney properties.

French Gulch.—The working force at the famous Glad-

Map of Arizona

gineer from Phoenix, is announced. Shipping ore already is available for sacking.—At Pearce the Commonwealth mill is running two shifts per day on Commonwealth ore taken out by lessees.—A few miles north of Christmas, a Gibson mill of 50-ton daily capacity is turning out rich gold-silver-lead concentrate from ore taken from a 2-ft. vein that is being developed by three tunnels.

Yuma.—The Arizona Barium Co. is a local organization that is to work a deposit of barite in the Mohawk moun-

tain. The mine was increased recently. All the tunnels and drifts have been cleared and re-timbered, where necessary, to make way for comprehensive development work.

Hayfort.—Alonzo and Lowell Layman have completed the erection of a 5-stamp mill on their gold property. Operations will be commenced at once.

Keddie.—C. R. Leonard and B. H. Smith are obtaining excellent returns from their gravel-mine operations in Butterfly valley. One small pocket recently yielded \$600.

Keswick.—The cable for the Mountain Copper Co.'s tram-line, from the Hornet mine to Matheson on the Southern Pacific, has arrived. The 32 towers are in place. Stringing the cable on the towers has been commenced. Six mules will be used in dragging the cable to its position on the mountainside.

Masonic.—S. L. Perini has recently uncovered a 3-ft. vein of high-grade gold ore on the Golden Anchor claim. The vein was traced and ore was exposed for a length of 50 ft.; assay returns indicate from \$27 to \$210 per ton. The mineral belt is an 'andesite formation' which has a width of about 1200 ft. A cross-cut adit was started with two shifts. Perini has a lease and option on the property.

Quincy.—The Jamison gold mine, near Johnsville, which is being operated under lease, will be worked throughout the winter. Sufficient ore is being produced to keep 15 stamps running for three shifts. Good results are being obtained.

Randsburg.—As the development in the district continues, it is noticeable that the best mining machinery is being purchased. The Bray lessees have successfully installed their new 700-cu. ft. compressor, and it is running smoothly, as is their new double-drum hoist. A new cage is on the ground.—The North Rand Silver company is now laying foundations for its electric hoist, compressor, tool-sharpening, and blowers.

Grady & Sill are shipping to the smelter at the rate of a car per day.—The Randsburg Silver Mining Co. is cross-cutting on four levels, 300, 400, 500, and 600 ft. The drift north on the 500-ft. level has advanced 210 ft. on the east vein. The cage is installed and is working satisfactorily. The new assay-office is completed and fully equipped.—The Silver Moon shaft is down 200 ft.—Erricart and Bernard are cross-cutting at 200 ft. on the K C N lease.

Near the Black Hawk territory, the Gimlet company is drifting, with good indications of silver ore at 50 ft. on the 150-ft. level.—The Black Hawk company has entered the list of gold producers; it has rented the Baltic 10-stamp mill.—The Yellow Aster still keeps 30 stamps dropping. With the Yellow Aster and the Black Hawk steadily producing, it is believed that many of the old mines will be revived.

Rough and Ready.—The Normandie-Dulmaine shaft is being sunk rapidly. Ore is being exposed on the surface. The property is owned by motion-picture actors of Los Angeles.—The recently incorporated Randolph Consolidated Gold Mines is developing orebodies on the old Grant ranch.

Yreka.—W. Howe and J. Hubbard have opened a 2-ft. vein of rich gold ore 12 miles from here on the Shasta river. Development will be undertaken.

COLORADO

Central City.—The Comet tunnel near the Rara Avis mine, within the city limits, has been taken under a three-year lease and bond by Vincent M. Ryan, of Chicago, and M. L. Judge and John Sullivan, of Lincoln, Nebraska. Miners are at work developing a well-defined vein carrying a 6-in. streak of ore assaying from \$40 to \$50 per ton.

Crosby.—The Mid West Mining Co. is installing machinery at the Resurrection shaft; the force of miners will be increased as soon as the plant is in operation. The property has been on the shipping-list for some time. The same company will operate the Mollie S., on Mammoth mountain, this winter and has sent out powder, steel, and supplies.—A new shaft is being sunk on the Mother Lode mining claim in the Sunnyside district. The vein exposed at surface will be cut by the shaft at a depth of about 50 ft.—Lessees on the Corsair and New York sent out shipments to the Arkansas Valley smelter, at Leadville, and the Durango smelter last week.

Cripple Creek.—Directors of the Cresson Consolidated have been called to meet on Tuesday, December 6, when it is expected the annual report will be ordered issued and action taken on dividends. The mine continues heavy production of from 8 to 10 cars daily, with an average value around \$15 per ton.—A series of flat veins has been opened on the Illawatha, a fractional claim of about 4½ acres adjoining the property of the El Paso Consolidated company on the south. The ore is of shipping grade. The property is operated under lease.—The Golden Cycle M. & M. Co. and the United Gold Mines Co., both controlled by the Carlton interests, will hold directors meeting shortly, when the declaration of a dividend is anticipated.—The Rose Nicol mine, on Battle mountain, is again active under lease; lessees have commenced shipping low-grade mill-ore.

Ouray.—The White Cloud Mining Co. will continue development work and add to the present ore-reserves during the winter months.—The Welch-Worland Mines Syndicate will operate both mine and mill this winter, employing 12 to 20 men underground and three shifts of 10 men each at the mill. The forces will be increased next spring.

Rico.—Supplies have been laid in at the Smuggler-Almont property at Duntun by the Mount Pleasant Mining Co.; six men will be employed on development during the winter months.—The Dolores Silver Mines, Inc., is shipping steadily and will continue winter operations.—The Rico Wellington reports that the drift from the Mountain Spring tunnel shows iron pyrite which has heretofore been associated with the ore deposit.

IDAHO

Coeur d'Alene.—The Hecla Mining Co. has declared a dividend of \$170,000, at the rate of 17c. per share. The forthcoming disbursement will increase the dividends for the year to \$670,000 and the grand total of dividend payments to \$9,005,000. Operations are proceeding steadily at the properties of the company.

The Silver Reef Mining Co. is reported to be working two shifts, making nine feet daily in the cross-cut. It is expected that it will be necessary to go 900 ft. to reach the orebodies found in the Silver Reef tunnel, the objectives of the present work.—The North Bunker Hill Mining Co. is drifting west on the big vein and is near an ore-shoot, according to reports. Two shifts are at work.

Hearings were begun before Judge Deitrich on November 30 to determine the amount the Federal Mining & Smelting Co. shall pay the Star Mining Co. as compensation for ore removed from Star ground. Claiming that the judgment is in error, and rendering the accounting under protest, the Federal company calculated the net proceeds to be \$71,786.14. The Star company, on the other hand, contends that the amount due it, including interest, is \$2,477,061.13 if the trespass be held inadvertent, and \$3,721,796.97 if the trespass is decided by the court to have been willful.

MICHIGAN

Houghton.—The recent statement that Seneca is expecting to produce copper at about 7c. per pound has aroused considerable comment. If it does that, it will be the lowest cost producer on record. In this connection, the costs of other companies are of interest. Seneca's neighbors, Ahmcek and Mohawk, also on the Kearsarge lode, produced copper at 11.5 and 13.1, respectively, in 1920; in 1917, Ahmcek's costs were 9.4 and Mohawk's 11.3. The costs of other companies in this district are as follows:

	1920	1917
Calumet & Hecla	15.3	13.1
Copper Range	13.9	12.5
Isle Royale	16.8	15.7
Osceola	19.5	13.8
Wolverine	18.0	11.7
Quincy	17.7	17.8

It also has been stated that Seneca is pointing toward a daily production of 7000 tons of rock from both the Seneca and Gratiot shafts. From four operating shafts Mohawk is producing 2600 tons daily, while the Wolverine's two shafts are yielding 1000 tons. Seneca would require additional milling facilities before it could handle such a large tonnage as contemplated. Rock taken out during the course of development is being treated at the Baltic mill, but when regular production is started, Seneca will utilize the two heads it has acquired from the Hancock Consolidated in the Lake milling plant at Point Mills.

Quincy is still striving to make 'a new dollar for an old one' on a curtailed basis of operation, providing work for as many men as possible to tide them over the winter. Only one stamp-mill is in operation and the 'rock' being sent to the mill keeps between four and five heads busy.

Early this month Mayflower will discontinue work temporarily on the 1700-ft. level and will move its four drills to the 1400-ft. level for an exploration of the ground where the vein was first opened by the shaft.

Preparations for a resumption of sinking at Gratiot No. 2 shaft, Seneca, are proceeding. Cement is now being poured for the shaft collar and a concrete foundation is being built for the new hoist. A survey is under way for the extension of the Mineral Range railroad-tracks to the Gratiot and Seneca shafts. It is this railroad which will serve Seneca when regular production is started. All drifts in Seneca are reported to be continuing in satisfactory ground.

The last copper out of the Lake district by boat this season was shipped on November 28 when a steamer left with an estimated cargo of 9,000,000 lb. This was one of the largest cargoes for several years. It is believed most of the copper is intended for export. The boat visited all of the smelters in the district. November shipments will compare very favorably with those of October. Copper has been moving in greater volume than generally believed and there is a distinct feeling of optimism.

MONTANA

Butte.—Contrary to published reports, the East Butte company will not shut-down its mine and smelter as a result of the suspension of production by the Davis-Daly company. The latter has been selling its copper ore to the East Butte company for treatment, but 60% of the ore smelted has come from East Butte's Pittsmond mine. The company is earning a profit on its operations and has not shown red-ink figures in a single month this year. It laid its copper down in New York when the price of the metal was around the 12c. level and made a profit of more than a cent per pound, so that it can be appreciated what the company is showing in the way of profits with the metal at current prices. And the management is selling only enough copper to keep itself in a liquid condition. Work in the new No. 4 shaft is progressing satisfactorily. This shaft has been raised from the 1800-ft. level and on November 20 was within 125 ft. of the surface. Barring any unusual obstacles it should hole through within a few weeks, when steps will be taken to equip it for actual mining.

Helena.—M. H. Welton is preparing to build a new plant for saving flour-gold in Golconda gulch, Jefferson county. He has just returned from New York, where he went to buy the machinery. The ore to be worked will be mined from the Bunker Hill and Bunker Hill No. 2.

The Revenue mine and mill and also the Missouri mine and mill are operating. The first is near Norris and the latter on Meadow creek in Madison county. The metal is gold. A concentrating mill is about ready to start at the head of Alder gulch.

A car of ore is consigned to the East Helena smelter from the Gray Eagle mine, Grass Valley district.

Cross-cutting is going ahead from the Howard shaft of

the Drumheller-Woldson group of claims in the Scratch Gravel hills. The width of the vein has not as yet been determined, but the shaft and drifts have exposed an extensive body of ore. — Gold ore of shipping grade is coming from the Fairview mine.

New work is going on in Grizzly Park, south of Helena. A boiler and pump has been installed at the Old Kennedy gold property, which is to be unwatered. Western capital is behind the enterprise.

NEVADA

Cherry Creek.—E. T. Godbe and George Z. Smith are producing 8 tons of ore per day from their lease on the Exchequer property, where operations are now under way on the 250-ft. level of the Imperial shaft. Shipments of silver-gold ore assaying \$45 per ton are being sent to the American Smelting & Refining Co., at Garfield, Utah. There are said to be many thousands of tons of \$15 ore in sight that might be profitably handled in a concentrator.

Ely.—Hilster copper is being shipped from the Nevada Consolidated company's smelter in train lots. It is reported that only 50 carloads of the 10,000 tons to be shipped remains. This should be disposed of within a few weeks.

Lovelock.—The Seven Troughs Reorganized Mines Co. has been formed as a consolidation of the Seven Troughs Coalition Mines Co., the Seven Troughs Mining Co., owner of the Fairview mine, and other small companies. The new company will undertake the driving of a tunnel which will tap the Coalition ground at a depth of 1100 ft. and will eventually go under Signal Peak at a vertical depth of 1420 ft. The tunnel will be 5700 ft. long from its portal to the side-line of the Coalition. This plan of developing the Seven Troughs properties has been under consideration for many years but because of so many conflicting interests and the cost necessary to perform the work it was never possible for one company to carry on the enterprise, but it is expected that through the consolidation ample finances will be secured. It will cost about \$200,000 to complete the work, according to John G. Huntington, of Reno, engineer for the company.

During the active development of the Seven Troughs district from 1907 to 1917 little attempt was made to take out the lower-grade ore, only the best being selected, and engineers state there is considerable low-grade ore already stored in the stopes. Water prevented deep mining through the Coalition shaft, and the property was closed down about four years ago.

Mina.—The flotation plant of the Simon Silver-Lead Co. is treating 100 tons of ore daily and will soon be handling 150 tons per day, it is expected. The process is said to be completely successful and shipments of silver-lead and zinc concentrates will start soon. The company is planning to develop its Simon Contact property, adjoining the main holdings, through the Simon Silver-Lead shaft.

Reno.—It is reported that ore-buyers representing the Wabuska smelter are visiting the districts in southern Nevada for the purpose of making contracts for the purchase of ore, in anticipation of starting operations at the smelter. A ruling of the Interstate Commerce Commission recently fixed a new low rate on shipments of copper ore from Plumas county, California, to the Wabuska smelter. This will make it possible for the plant to be re-opened and for the smelting company to purchase silicious gold and silver ores for treatment. The rate from Tonopah to Wabuska will be approximately \$5 per ton as against \$20 for shipment to the smelters in Salt Lake valley.

Spanish Belt.—The 50-ton mill of the Consolidated Spanish Belt Co. has been given a trial run and has proved successful. A recovery of 88% of the silver is made by using flotation, the concentrate averaging 170 oz. silver, \$6 gold,

4% lead, and 2% copper. Years ago the mine produced high-grade ore, but the efforts of the present company have been directed toward the development of a large reserve of low-grade ore; 10,000 ft. of underground work has blocked out a large tonnage containing 15 oz. silver per ton. R. Dean Bradley is superintendent of the new plant.

Tonopah.—After refusing to join with other Tonopah mining companies in a reduction in the wage-scale on April 16 and maintaining the old scale since that time, the West End Mining Co. on December 1 posted notices reducing wages 75c. per day, making the scale uniform in all mines. The reduction will become effective on December 16. The West End avoided a strike in the spring by refusing to join the other companies in the lower wage-scale and was one of the few companies to maintain the old scale. While a strike was on at the other mines the West End continued operations and it was partly because of contributions made by its workers to the miner's strike fund that the strike was prolonged. The higher scale has also been maintained by the West End since the Tonopah strike was declared off.

UTAH

Alta.—The width of the orebody recently opened at the Alta Tunnel & Transportation Co.'s mine shows no signs of decreasing. At present the face is 20 ft. wide and 5 ft. thick, and the deposit is said to be dipping to the south. F. V. Bodfish, manager of the mine, is convinced that the most economical method of mining is to extend the drift from the main level until it cuts the deposit. The sixth lot recently settled for by the Murray smelter gave net returns of \$43 per ton.

American Fork.—Mining is active, owing to the mild weather. Between 15 and 20 teams are engaged in hauling ore and supplies. The tramway between the Pittsburg mine and the Pacific mill was completed and placed in operation in December. John Cleghorn, manager for the Globe Mining Co., reports an excellent showing of ore in the property by the American Leasing Co. The Leasing company has been driving a drift through the Globe property and has found ore, which now has a width of between 7 and 8 ft. A 50-ton shipment has been made to the International smelter.

Eureka.—A new 300-hp. motor has been received and installed at the Eagle & Blue Bell mine. Operations have been curtailed at times on account of the burning-out of the old motor, and the new one has been purchased to prevent similar delays in the future. William Owens, superintendent, reports conditions at the Eagle & Blue Bell and Victoria mines as excellent.

Ore shipments for the week ended November 26 totaled 170 cars, as against 164 cars for the preceding week. The Tintic Standard shipped 55 cars; Chief Consolidated, 44; Victoria, 16; Dragon, 16; Iron Blossom, 13; Eagle & Blue Bell, 7; Centennial-Eureka, 4; Colorado, 3; Swansea, 3; Grand Central, 3; Empire, 2; Mammoth, 1; Bullion-Beck, 1; Castleton lease, 1; Sunbeam, 1.

Park City.—The Park-Utah Mining Co. is driving a long drift for the purpose of developing what is known as the Frog Valley fissure. This drift will have its terminus in Deer Valley, a short distance from the Judge smelter. Geologists who are familiar with the eastern section of the district believe this exploratory work will result in uncovering orebodies as large and high-grade as any heretofore discovered at Park City. The work now under way by the Park-Utah is the first real attempt that has been made to explore that section.

A shipment of screened material from the Iron Drift at the Silver King Consolidated property netted \$50 per ton, or \$1000 for the lot. The screenings were collected from pyrite; it is reported that there is a considerable amount of this material available for shipment.

Ore shipments for the week ended November 26 totaled 2110 tons, of which the Judge allied companies shipped 911; Silver King Coalition, 721; Ontario, 428; and the New Quincy, 50. Shipments the previous week totaled 2279 tons.

The directors of the Silver King Coalition Mines Co. declared a dividend of 15c. per share, payable January 2. This is the second dividend declared this year. It will call for the payment of \$187,500, and bring the grand total up to approximately \$15,600,000. The building for the new 450-ton concentrator is finished, and machinery is being installed. It should be ready for operation early in the new year.

The New Quincy Mining Co. will devote its entire efforts on development of the orebody opened in a winze from the 700-ft. level from the Little Bell shaft. All other development work was stopped on December 1. A second drift has been started to follow the ore out from the winze. The third shipment of 50 tons, made from the recent strike, gave returns of 0.04 oz. gold, 54.7 oz. silver, 13.5% lead, and 1.16% copper, netting the company, after deducting freight, smelting, and sampling charges, \$46.67 per ton.

Salt Lake City.—The Mining Committee of the Salt Lake Commercial Club has asked Governor Charles R. Mabey to appoint an honorary State Geologist, and to recommend in his next message to the Legislature the creation of a permanent position of State Geologist. The Committee holds the opinion that Utah has expended practically nothing to promote the mining industry, which is the greatest factor in the industrial life of the State. The attention of the Governor is also called to the fact that practically every other State in the Union has a State Geologist, and that Utah, by reason of its large and varied mineral output, also should have such an official.

BRITISH COLUMBIA

Alice Arm.—Work at the Bellevue mine, in the Illiance River district, has been suspended for the winter. The summer's operations are said to have been satisfactory; a good deal of surface-trenching and stripping has been done, and a belt of ore 25 to 50 ft. in width has been traced for 3000 ft. The ore is said to carry about 4% lead, 5% zinc, 20 oz. silver per ton, and a little gold. A tunnel has been started to develop the orebody at depth.

Hazelton.—J. S. Kelley has sold the Judges group, in the Babines, to an English syndicate for \$85,000.—P. J. Higgins and associates, who are driving a tunnel on the Silver King group, at Driftwood creek, to develop a promising lode that has been exposed at the surface, have cut a strong vein 60 ft. from the portal that had not been discovered on the surface. The vein is well mineralized with gray copper and arsenical pyrite.

Nelson.—W. B. Pool, manager of the Reno mine, reports an important discovery at the Nugget mine. A long cross-cut was driven from the Motherlode workings to cut the Nugget vein last year; a 12-ft. body of ore, supposed to be the Nugget vein, was cut, and drifts were opened in each direction on the vein. Recently the cross-cut was continued to develop other veins on the property, and it soon ran into a large orebody, which is believed to be the real Nugget vein; the vein previously cut being only an off-shoot from the main vein.—James Fisher and partners are about to explore the orebodies of the Monarch mine, at Hall, with a diamond-drill, which is now on its way to the property.

Princeton.—J. J. Warren and W. M. Archibald, of the Consolidated M. & S. Co., have been looking over the Voigt mining claims, at Copper Mountain, and it is rumored that the Consolidated is making negotiations for the property. The Consolidated has a smelter, refinery, and rod-mill capable of turning out 50 tons of finished rods daily, but practically no ore to feed it. The Voigt claims adjoin those of the Canada Copper and are said to be equally good.

Vancouver.—The coroner's jury, which has held a number of sittings since the Britannia Beach disaster and which visited the scene, has brought in a sweeping verdict against the Britannia M. & S. Co. and its officials. It says in part: "The disaster was caused by what is known as the railroad fill, or dump, giving way, and we, the jury, declare that it was criminal neglect on the part of the Britannia Mining & Smelting Co. for deliberately allowing the blocking of a natural mountain stream, known as Britannia creek".

MEXICO

Cananea.—During its present shut-down, the Greene-Cananea Copper Co. is conducting a broad program of underground development and surface expansion. It is remodeling and enlarging its mill and smelter, adding over 500 tons per day to the capacity of its reduction works. In line with the deflationary tendency in the United States, Mexican

Ojinaga.—Vicente Itel is opening up the Centenario group of gold mines in El Cordon mountains at Batopilas.

The Tres Piedras group of silver-lead mines situated in the Milpillas mountains of the Cuahuahachile district has been filed on by G. Delgado. The property adjoins the old Tres Amigos and Tres Reyes mines, which have produced considerable ore.

Durango.—Hilario Lozoya, accompanied by a number of prominent American capitalists, arrived here recently to inspect mines and railroads in the Guanaveci district. They will go over the route of the proposed railroad line from Tepihuanes to Guanaveci, in which they are interested.

Herald McLeod Cobb, representing the Mines of Guanaveci Co., has recently taken up the Confin group of gold-silver mines in the Guanaveci district. The property lies adjacent to the Nuevo Porvenir, La Tercera, and La Sopresa.

On Howe Sound, British Columbia

labor, particularly in the mining district of Sonora, has had a sharp reduction in wages. During the height of the war, ordinary peon labor was getting as high as \$4 gold per day with a consequent expansion in Greene-Cananea's cost. During the past few months, however, the wage-scale has undergone a revision and the company will be able to show a much lower cost when the word is given to resume mining. Carried on the liability side of the balance sheet is an item which may be ultimately turned into an asset. At the close of last year the company had a reserve for accounts and wages payable and "taxes accrued" of \$2,026,526. A large amount of this was money the company had paid as taxes to the Mexican government under protest. This, however, is being discussed now with Mexican officials and there may be a reduction of no small proportions in the accrued tax item.

Chihuahua.—Miss Sofia Pengoechea has applied for titles to the Ampliacion de Carmen group of gold-silver mines in the mining district of Coyame, adjoining the Carmen, Sofia, and Walkira mines.—Felipe C. Schaefer has located five claims at Guadalupe y Calvo, which are to be titled the Hidden Treasure group.—Ernest Underwood has located the Coronado mines in the Parral district. Some good gold, silver, and lead ores have been extracted during preliminary development.—Alfredo Quijano, of Chihuahua City, has taken up 25 pertenencias in the San Carlos mountains near

Torreon.—James I. and J. C. Long and S. E. Gill, officials of mines in Parral and the Parral & Durango railroad, have been touring Mexico in company with a number of prominent mining men and bankers. In the party were A. J. McQuatters, of the Alvarado Mining Co.; Louis E. Stoddard and J. L. Day, of New Haven; William H. Wright, engineer; Franklin Remington, of the Foundation company; J. F. Shaw, banker; Kuno B. Heberline, formerly manager for the Penoles Mining Co.; G. E. Stanwood, Boston banker; and J. G. McNary, president of the First National Bank of El Paso. At Chihuahua they visited Governor Ignacio Enriquez, and at Parral an investigation was made of the mining properties of the Alvarado Mining & Milling Co., the Refugio Mining Co., and the Parral & Durango railroad. They are now on their way to Mexico City, where they will call on President Obregon and return to the United States by way of Tampico, where they will make a study of the oil-fields.

ONTARIO

Cobalt.—The La Rose Consolidated has decided to go deeper on the Violet vein where results on the 530-ft. level have been satisfactory. A shoot of ore 225 ft. in length has been developed, both ends of which are still in ore. The winze is being put down to 600 feet.

Goudreau Township.—Following the satisfactory showing made in the sinking of the shaft on the Porter mine \$200,-

000 will be spent in developing the property. Other holdings in the area are showing up well. Sixteen claims held by Thomas Powell and others, some distance east of the Porter, have been optioned by a Detroit syndicate.

Kirkland Lake.—The plan for the reorganization of the Teck-Hughes will be submitted to a special meeting of shareholders called for December 7. It is proposed to increase the capital from \$2,500,000 to \$4,000,000 and to provide for the sale of unissued stock at 15c. per share. The stock is to be offered to shareholders on the basis of four shares of the new for five of the old, leaving the unsubscribed balance available to the bondholders. The outstanding bonds of the company amount to \$500,000, with arrears of interest to the amount of \$135,000. An issue of five-year 7% first-mortgage bonds is proposed, to retire the bonds now due.

Porcupine.—The McIntyre has declared its regular 5% dividend, payable on January 2. R. J. Ennis, general manager, states that the geological structure at the present depth of 1875 ft. is such as to indicate a long life for the mine. The management has decided to sink the shaft 100 ft. lower. When this has been accomplished and the lower levels opened, the company, provided an enlarged supply of electric power is secured, will proceed with the construction of a mill on the north side of Pearl lake. This will be in addition to the 250-ton enlargement previously announced.

The Nipissing has drilled a fifth hole on the Rochester property and will continue the work of exploration. The management is reticent as to results, but it is stated that veins with encouraging gold content have been found.

South Lorrain.—It is officially stated that the Mining Corporation of Canada has taken a working option on the Haileybury-Frontier property. The mine has been developed at the 150-ft. and 300-ft. levels, on both of which a good deal of commercial ore, including some high-grade, has been opened. The Mining Corporation is employing extra men and will make considerable additions to the mining plant.

STRAITS SETTLEMENTS

Penang.—One dredge has been put into operation on its Malay tin property by the Yukon Gold Co. Two others will be set in place during the next few months. The Yukon company plans to become the largest tin producer on the entire Malay peninsula. Because of the excessive export duty levied by the local government, however, the company will market its output on the ground to Straits smelters. With tin at 28c. per pound this market has dropped below the average cost of production and has forced the cessation of mining and shipping from Bolivia, from which country comes the bulk of tin ores and concentrates sent to America. Thirty-cent tin would enable most producers to break even, but even this price would be 10c. below the average of the past 15 years. The new plant of the Yukon company in Malay will involve the expenditure of \$5,000,000, and this amount will eventually be financed through a new security issue. Leading interests in the company will continue to advance required funds until such time as permanent financing can be accomplished.

YUKON TERRITORY

Dawson.—Notice has been received here that the Federal government has suspended the embargo against the exportation of ores from Yukon Territory for 12 months, in order to facilitate the movement of ore from Mayo Landing when navigation opens in the spring. The embargo originally was imposed as a war-measure, and there seems to be no good reason why it should not have been removed entirely.—A new gold find is reported on a tributary of the Stuyahok river, 35 miles north-west of Marshall, in the Fortuna Ledge district. The deposit is said to be 25 ft. deep, and is running from 85c. to \$4.50 per pan. A number of claims have been staked, and arrangements have been made for extensive open-cutting operations next spring.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Joseph Errington is at Vancouver.

H. H. Webb is at the Fairmont hotel.

F. W. Bradley has returned from Alaska.

Walter Hovey Hill is at Pittsburgh, Pennsylvania.

Frank M. Smith, of Spokane, is on his way to New York.

George W. Backeland, recently of Golden, Colorado, is in Paris.

George E. Stephenson has returned from New Zealand to London.

Andrew Nisbet has moved from San Leandro to Natoma, California.

R. D. Winno is at Dundu Angola, in the Belgian Congo, West Africa.

Joseph Clark has moved from Louisville, Ohio, to St. Louis, Missouri.

J. H. Rodgers has moved from Felix, California, to St. Louis, Missouri.

Louis J. Joubert has moved from Comptonville to Oakland, California.

Walter F. Brown has left Chichagoff, Alaska, and is now at Clarkston, Washington.

Eric Huntley has been appointed manager of the Laloki copper mines in New Guinea.

James Martin, recently of Yucca, Arizona, is now at the Cedar mine, Kingman, Arizona.

E. E. Slack, of Warren, Arizona, will be at Cananea, in Sonora, for about three months.

D. C. Jackling is in New York. He expects to return to San Francisco before Christmas.

Stanly A. Easton, general manager for the Bunker Hill & Sullivan company, is at Washington.

M. J. Dailey, mine manager for the Silver King Coalition Mines Co., is visiting at O'Neill, Nebraska.

Arthur W. Allen, Associate Editor of the 'M. & S. P.', has been visiting Ajo and Bisbee, in Arizona.

John Dern is seriously ill at his home in Salt Lake City. He returned from Europe about a month ago.

D. J. Argall, mine superintendent of the Perseverance mine, at Thane, Alaska, is at San Diego, California.

E. H. Wells is president of the New Mexico State School of Mines, Socorro, New Mexico, in place of A. X. Illinski.

T. H. Jenks has returned to Los Angeles from Sinaloa, Mexico, and is recovering from a severe attack of malarial fever.

Walter W. Wishon is now residing at Kingman, Arizona, where he is engineer to the Katherine Big Four Mines Corporation.

John Smeddle, who has been at the Red Lion mine, at Oatman, Arizona, is now with the Union Corporation of South Africa at Guadalupe, in Zacatecas.

Walter Douglas, president, P. G. Beckett, general manager, and H. H. Stont, metallurgist for the Phelps Dodge Corporation, were members of a party that inspected the mines and works at Clifton recently.

Henry A. Tobelmann, metallurgist for, and associated with, the New Cornelia Copper Co. and the Calumet & Arizona Mining Co. for the past 16 years, has resigned. He will leave Ajo for New York early in January.

Thomas H. Teal, manager for the Liberty Mining & Reduction Co., at Montezuma, Colorado, is at Sawtelle, California, owing to the closing of the mine for the winter.

Zinc-dust, cents per pound.....	9.00-9.50

EASTERN METAL MARKET

(By wire from New York)

December 5—Copper is active and higher. Lead is moderately active and firmer. Zinc is stronger and there is more business.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

ADVANTAGES OF THE ELECTRIFICATION OF RAILROADS

Some of the striking advantages of electric operation of the railroads are stated by the U. S. Geological Survey. These advantages include the conservation of national resources, both coal and labor; an increase in the capacity of main and yard tracks; an improvement of the physical condition of terminals and an increase in the value of the property, as shown by the New York Central and Pennsylvania terminals in New York City; benefits both to the travelling public and to residents along the route through the elimination of noise and smoke; the possibility of providing multiple level terminals and freight warehouses; and economy in operation through the use of fuel and machinery for generating energy by a few skilful operators in economical stations as contrasted with a large number of technically ignorant operators with small uneconomical machines.

The electric locomotive is equipped with meters that afford complete knowledge and control of operating conditions and that are also a valuable guide in handling the train, particularly in starting a long heavy train. With electric traction the economy of the entire sequence of operation is not dependent upon one man, as it is with steam. Operation is therefore no longer a matter of individual judgment, skill, or fidelity. It is this unfortunate human element that nullifies the theoretical advantages of the "full-jawed movement" steam locomotive. The effectiveness of the device for increasing efficiency and capacity necessarily depends on the intelligence and faithfulness of the average engineer.

The inherent wastefulness of the steam locomotive is proved by its own advocates in their claim that "40% of its coal can be saved by the careful use of auxiliary devices". Then why be skeptical, it is asked, of a saving of 60% by a modern power-station, which has all these devices in greater completeness and, in addition, has brains to use them?

The speed of different classes of trains run by electricity will be more nearly uniform. Much heavier trains can be handled, and at the same time light freight-trains can be moved at the speed of local passenger trains. It has been proved that for the heaviest freight service, such as mountain-grade work, the electric locomotive is superior to the steam locomotive, but its superiority in handling light freight at high speed is not so generally understood.

The electric locomotive can be kept at work on the road for 20 hours per day, and if operated at an average speed of 25 miles per hour it can run 500 miles per day. This mileage, however, is double that of the electric passenger engines now used on the New York, New Haven & Hartford line and is higher than would be obtained as an average, but there is every reason to believe that an average between 250 and 500 miles can be made.

MONEY AND EXCHANGE

Foreign quotations on December 6 are as follows:

Sterling, dollars: Cable	4.08%
Demand	4.00%
Franc, cents: Cable	7.63
Demand	7.65
Lira, cents: Demand	4.41
Mark, cent:	0.57

Eastern Metal Market

New York, November 30.

The month closes with a record of having been one of the most active in some time, though in general the markets are all a little quieter than a week ago. Prices are well sustained for the four leading metals. The Thanksgiving holiday on November 24 has had the usual retarding effect.

Copper prices have advanced moderately and buying and inquiry are good.

The Straits tin market has turned very quiet.

Lead continues in steady quiet demand at firm prices.

Demand for zinc is very light, but prices are fairly firm.

IRON AND STEEL

There is no development in prices. On smaller lots of plates, shapes, and bars 1.60c. is commonly the basis, and as heretofore, larger business is done at 1.50c. The American Sheet & Tin Plate Co. opened its books on November 23 for 1922 business at 3c. for black, 4c. for galvanized, and 2.25c. for blue annealed sheets. Independent companies are naming these prices also, but the present inactive market has not seriously tested them. Winter operation of tin-plate mills promises to be on a good scale, in view of the thorough depletion of stocks. Welsh makers of tin plate, with 40 shillings ocean-freight to Vancouver, took 150,000 boxes there lately at close to \$4.25 per box, duty paid. This is well below any American competition.

COPPER

Some sellers report a quieter market while others state that inquiry and sales keep up at a satisfactory pace. At any rate the situation is considered excellent and the tone firm. A good business has been done, particularly for future and first-quarter delivery and prices have advanced moderately. Electrolytic copper for this year's delivery is now quoted generally at 13.62½c., delivered, or 13.37½c., New York or refinery, while for January and first quarter the minimum is 13.75c. delivered, with some sellers quoting ¼ to ½c. higher. Sales for foreign consumption are exceedingly good with Germany and England the largest buyers. Exports to Germany for the first nine months and the year have been more than those to England and France combined.

TIN

The market has turned very quiet in decided contrast to the marked activity which prevailed a week ago. The Thanksgiving holiday is one cause, doubtless, but the temporary satisfying of the large needs is another. Of still more influence is the higher London market where prices have advanced sharply this week. The firmer and higher value of exchange is a factor. Actual buying of Straits tin has been negligible and there is very little to report. Prices are firm to higher as influenced by the factors enumerated, with spot Straits tin quoted yesterday at 29.87½c., New York. Quotations yesterday in London were about £2 per ton higher than a week ago at £163 5s. for spot standard, £165 for future standard, and £163 10s. for spot Straits. Arrivals thus far this month have been 2525 tons of which only 50 tons have come in at Pacific ports. The quantity reported afloat is 1150 tons. Quotations for American electrolytic tin are nominal.

LEAD

The chief matter of interest in the lead market is the growing strength of the British market where lead appears to be scarce and where prices are advancing. In the last week the London market has gone from £24 15s. to £26 per ton, for prompt delivery, due to the fact that there is less metal available from Mexico and Spain, in particular. The market here continues in its rut of steady demand at firm

unchanged prices. The leading interest continues to quote 4.70c., New York and St. Louis, while in the outside market quotations are 4.35c., St. Louis, and 4.70c., New York.

ZINC

Buying is light and spasmodic and apparently confined to the immediate needs of consumers, particularly galvanizers. With a view to keeping down stocks for inventory purposes, purchases are generally of a hand-to-mouth character. Added to this is the lack of selling-initiative by most large producers. The market is therefore a waiting one, but the tone is cheerful and the outlook bright. Due to offerings from at least one source late last week at close to 4.60c., St. Louis, the market shaded slightly, but it is now firm. Prime Western in wholesale lots for early delivery is quoted at 4.65c., St. Louis, or 5.15c., New York.

ANTIMONY

Wholesale lots for early delivery are quoted unchanged in a quiet market at 4.50c., New York, duty paid. Jobbing lots are about ¼c. per pound higher.

ALUMINUM

The suspicion entertained for some time that the leading domestic producer was selling under its quoted price of 24.50c., f.o.b. plant, for wholesale lots of virgin metal, is now confirmed as a fact by the announcement that since about November 15 its price has been 19c. This puts it nearly on a par with the quotations of importers of the same grade of 17 to 18c., New York, duty paid.

ORES

Tungsten: The market is devoid of interest, partly due to the reluctance of holders of ore to dispose of their supply at prevailing prices. One report is to the effect, however, that some have sold their stocks to obtain cash before the year-end. Prices are a little lower as a result with the minimum at \$2 per unit for Chinese ore; other grades are higher.

Molybdenum: A few sales are reported at 45 to 48c. per pound of MoS₂ in 85% concentrates.

Manganese: Stocks are heavy in consumers hands and there is absolutely no demand. Prices are nominal at 20c. per unit, Atlantic seaboard, for high-grade foreign ore. Imports were heavy in October at 36,760 gross tons as compared with only 14,823 tons per month for the third quarter.

Chrome: Chrome-ore stocks are also reported as heavy and there is no new demand nor is any expected before 1922. Rhodesian and Indian ores are quoted at \$21 to \$22 per ton c.i.f. Atlantic ports.

FERRO-ALLOYS

Ferro-manganese: There is almost no activity, the only business heard of being 100 tons sold by the Steel Corporation on a basis of \$60, Pittsburgh. There is a rumor afloat that British prices are to be raised, but it is unconfirmed. Quotations for British and domestic alloy are unchanged on a basis of \$58.35, Atlantic ports. Imports in October were heavier than in some months at 1943 tons, which compares with 499 tons per month for the third quarter.

Spiegeleisen: The market is flat with quotations unchanged at \$25 to \$26, furnace, for the 20% grade.

Ferro-tungsten: There is no demand and prices are nominal at 40 to 45c. per pound of contained tungsten in the domestic alloy and at 50c., duty paid, seaboard, for the foreign.

Ferro-silicon: The market for 50% ferro-silicon is firm at \$60, delivered, per ton, with no activity reported.

Ferro-chromium: Quotations for standard alloy vary from 10 to 14c. per pound of contained chromium, with no demand recorded.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

A BELT-CONVEYOR MADE OF STEEL

In a recent issue of a well-known engineering publication the following statement was made: "By means of belt-conveyors large carrying capacity is combined with low power-consumption. Belts usually take 50% of the power used by other conveyors, so the problem of the engineer is really to see whether or not belt-conveyors can be employed". It is evident from this that belt-conveyors are recognized for their efficiency; a study of industrial conditions reveals the fact that they have been extensively used.

When a belt-conveyor is mentioned it is natural for the engineer to picture in his mind a canvas, balata, or rubber belt. To speak of a steel belt-conveyor immediately brings one into a foreign field and questions arise because of the fact that they have not been used in this country. The Sandvik Steel Works in Sweden has had a wide experience covering about 30 years in the cold-rolling of steel. About 12 years ago it began to make steel belt to be used for conveying purposes. In various phases of industry it has met with decided success.

The flexible-steel belt, known as the 'Sandvik' belt, is made from the very best Swedish charcoal-steel with a percentage of carbon of about 0.65; it is cold-rolled, hardened and tempered by a special process, which was originated by the Sandvik works and perfected after many years

To date, about 1300 steel belts have been made for handling coal, coke, charcoal, iron ore, concentrate, copper ore, phosphate ore, sulphur ore, rock, and numerous other materials. The steel belt-conveyor is especially suitable for

A Sandvik Steel Belt, 285 ft. Long, 16 in. Wide, and 0.035 in. Thick. Weight, 550 lb.

Left—Adjustable Scrapers Showing How Sandvik Belt Can Be Discharged at Different Points. Right—Interior View of an Iron-Ore Concentrator

of experiment. The Sandvik works has always made a specialty of high-grade cold-rolled material, and for this purpose it has acquired controlling interest in a large number of the world-famous Swedish mines producing iron ore low in sulphur and phosphorus.

conveying warm, sticky, sharp, or abrasive material which rubber and fabric belts cannot handle satisfactorily. The advantages of the steel belt over apron-conveyors and wire-woven belts are the elimination of heavy maintenance costs, power consumption, and the spilling through joints and interstices.

The 'Sandvik' belt has an especially hard, smooth, and dense surface which accounts for its great durability and high wear-resisting qualities. The belt, when installed as a conveyor with standard-size pulleys, is subjected to a working stress of 28,000 to 30,000 lb. per square inch when traveling over the pulleys. The manufacturing process also imparts properties that make it particularly adapted for conveying hot material. By the special method of heat-treatment, hardening, and tempering the Sandvik belt acquires better rust-resisting qualities than common cold-rolled steel of similar composition.

As compared with flat rubber belts of the same width, the steel belt possesses greater transverse rigidity and therefore a higher capacity, as the edges, even with a one-sided load, do not yield in a downward direction. This allows a relatively broader part of the belt to be used for carrying the load. These attributes are obvious and are due to the fact that the steel belt is less flexible than the textile fabric.

As a result of the unavoidable vibration in a textile belt while running, the material conveyed has always a certain tendency to spread, and therefore the width of the loading-area in most cases can not exceed one-third of the width of the belt, whereas, in the case of a steel belt, two-thirds of the width may be used without danger of spillage, on account of the fact that it runs smoothly. This fact is also partly accounted for by the greater rigidity of the steel belt, which allows greater distances between the supporting rollers, thus less disturbance of the material.

A special feature is the remarkable ease and simplicity with which material can be discharged at any desired point along the conveyor without the use of cumbersome and expensive trippers. The belt does not stretch and the tension devices are therefore very simple, as they only have to take up trifling variations in length, caused by changes of temperature. The 'Sandvik' conveyor is designed in two ways, either with the conveying strand sliding on a wooden support, sometimes fitted with skirting boards, trough-like, the return strand being supported on idlers, or else both strands of the band are carried on rollers in the usual fashion. For carrying heavy, hard, and abrasive materials the roller supported type is preferable, the material being placed centrally on the belt and the edges left free, as is the general practice with flat-band conveyors. Steel belts can not be troughed like textile bands, which reduces their capacity for the same width, but this fact is compensated for since, as previously mentioned, a flat steel belt has a wider loading-area.

It is obvious that the introduction of the steel belt has widened the field of application of the belt-conveyor, which previously had not been suited for conveying hot and sticky materials when only the textile and rubber belts were available. Sharp-edged cutting materials, such as glass, can also be transported on this belt. Finally, material which, on account of its high temperature, can not be handled on belts of rubber or balata, can be handled by the steel belt. All these are advantages which open up a wider field of usefulness for the belt-conveyor, and should be welcomed by the engineer interested in the handling of materials.

THE SULLIVAN DISPLACEMENT-PUMP FOR ELEVATING ACID BY COMPRESSED AIR

For several years past the use of compressed air for pumping acid has been widely extended, as the more modern principles of the air-lift method have been applied securing greatly increased efficiency and convenience.

Ordinary simple or even compound air-lifts have their limitations in this field, however, due to the low factor of submergence frequently encountered. The saturation of the air by the acid has also resulted in undesirable fumes and in losses due to precipitation at the point of discharge.

The Sullivan pneumatic-displacement pump has been designed to avoid these difficulties, while embodying many of the advantages typical of the air-lift system, and others peculiar to itself.

The pump consists of two cylinders or tanks, side by side, with a common inlet and a common discharge opening, each provided with check-valves. The tanks fill by gravity, and are alternately emptied of their contents by direct air-pressure, which carries the liquid being pumped to the desired elevation. The filling and emptying of the tanks is controlled by the Sullivan automatic switch, which is placed above the level of the acid and operated by air from a line independent of that which supplies the tanks. The operation of the switch, by alternately admitting compressed air to each tank, secures a continuous discharge of acid into the storage tank or basin.

By means of a single adjustment, made by turning a control-valve, the suction-lift and capacity of the pump are varied to suit changing requirements. The action of the

switch is fully automatic, and it will run continuously as long as the air-supply is maintained. Among the advantages of the new displacement pump are the following:

1. The liquid to be pumped does not come in contact with any moving parts, such as floats, except the inlet and discharge check-valves.

2. Clearance losses are avoided, since the automatic switch leads the expanded air from the empty tank into the full cylinder before admitting live air to the latter, thus filling the lines and clearance spaces.

3. Power and time losses in overcoming inertia are obviated by this method of re-using the exhaust air, thus starting the acid before live air is admitted.

4. The speed of switching is governed effectively by an accessible valve, without other adjustment or change of parts.

5. The air-pressure to the switching apparatus is regulated by an independent diaphragm reducing-valve, securing positive and equal timing of the switch-movement, regardless of the pressure in the air-receiver.

6. There is no precipitation loss or emulsification of the acid being pumped. The compressed air does not mingle with the liquid, but merely exerts direct pressure upon its surface.

7. The pump and exposed parts may be made up of steel, cast-iron, bronze, or other materials designed to resist the chemical action of the acid to be handled.

8. Pumps may be supplied for any desired capacity and lift, and for liquids of any specific gravity, within a wide range.

CREDIT TO THE U. S. BUREAU OF MINES

In this department of the 'Press' for November 12, mention was made of an interesting moving-picture exhibit called 'The Story of Rock Drilling'. The fact should have been stated that this film was prepared by the U. S. Bureau of Mines in co-operation with the Sullivan Machinery Co. The equipment shown is all of Sullivan manufacture and the production was financed by the Sullivan company, but credit for the idea and for the distribution of the film is due to the engineers of the U. S. Bureau of Mines.

COMMERCIAL PARAGRAPHS

The Associated Machinery Corporation is a new organization, consisting of the Pawling & Harnischfeger Co. of Milwaukee, the Insley Manufacturing Co. of Indianapolis, the Chain Belt Co. of Milwaukee, and the Novo Engine Co. of Lansing. Its purpose is to co-operate in the development of trade in India, Ceylon, and Burma.

The Koppel Industrial Car & Equipment Co., large manufacturer of industrial cars, narrow-gauge track materials, etc., has opened a new district office at Kansas City, Missouri, in the Railway Exchange Bldg. Harry C. Kraft, formerly with the New York office, has been appointed manager for the Kansas City district.

Dwight P. Robinson & Co., engineers and constructors of New York, have recently secured contracts from the Middletown Hotel Co. for the construction of a five-story hotel at Middletown, Ohio, and from the Sterling Salt Co. of New York for the design and construction of a salt warehouse with conveying equipment at Cuyierville, New York.

The Mutual Truck Co.'s plant and equipment at Sullivan, Indiana, will be offered at public sale by the receiver, on December 22. The sale will include 12 acres of land with siding to the C. & E. I. and Illinois Central railroads; a large modern brick building with steel-truss roof; heating-plant, machine-tools, drawings, blue-prints, and a miscellaneous stock of materials and parts for building a 24-ton motor-truck. The First National Bank, Sullivan, Indiana, is the receiver, and E. D. Maple is the trust officer in charge.

T. A. RICKARD, Editor

THE annual meeting of the Northwest Mining Association will be held at Spokane on February 14 and the four days following.

SETTLEMENT of the civil war in Ireland and the unmistakable success of the Washington Conference must be causes of annoyance to Hearst, Brisbane, and their crew of mischief-makers, for these events have decreased the chances for international conflict. If now Hearst and his yellow papers could be given appropriate sepulture in deep water off the island of Yap, we would call it a real Merry Christmas.

LABOR disputes have laid a heavy hand on the industrial progress of Australia. Since the Broken Hill Proprietary Company started to operate its steel works in April 1915, nine serious strikes have affected operations; these covered a period of 96 weeks, or about 30% of the time. The trouble arose almost entirely as the result of factors over which the company had no control. When the strike was ended at the company's Broken Hill mine in November 1920, work was resumed at once and was continued for about two months, when labor was found to be so costly, in consequence of increased wages and shortened working hours, that operations were again suspended and the mine has since remained idle. Whatever the arguments for or against industrial disputes, there is no gainsaying the fact that they cause a disorganization and an economic waste that is deplorable, from the national and from the individual viewpoint.

PROFITEERING, or charging all one can get, is not a new art of the twentieth century; witness the testimony of Mr. John S. Collins, as related in the 'Saturday Evening Post'—of Burlington in Iowa, by the way, not of Philadelphia. Mr. Collins went to Silver Bow, Montana, in the early 'sixties. The settlement, which has since grown into the city of Butte, consisted at that time of two buildings, one of which was owned by a storekeeper named Dorgan. Along Silver Bow creek and in the neighboring gulches about 250 men were digging for gold. Collins started a store in opposition to Dorgan, his stock being one wagon-load of goods that he had hauled 100 miles, over the continental divide, from Virginia City. The 'going' price for a 98-lb. sack of flour was \$50, but during January the snow became unusually

deep on the divide, and Dorgan conceived the idea of raising the price of flour to \$75, in view of the fact that the arrival of freight by team from Virginia City before spring was unlikely. Collins, it seems, with uncanny prescience, declined to join his fellow merchant. The next Sunday, so the story goes, two wagon-loads of miners called at Dorgan's store and without preliminary parley proceeded to load their wagons with flour, beans, rice, and sugar. For the goods appropriated they paid Dorgan, in 'dust', 25% of his price, which still left him an excellent profit; and as they departed they warned him that 'another attempt at profiteering would find him dancing on nothing at the end of a rope'. Unfortunately life is more complicated in our day and generation.

BRONZE will be used as a protective covering for 85% of the surface of the steel in the proposed Hudson River suspension bridge, the new \$100,000,000 structure that is to connect Manhattan Island with the New Jersey shore. As a consequence it is estimated that \$400,000 will be saved annually in the expense of maintaining the bridge, this sum representing the cost of renewing the paint, a procedure that will be obviated by the protection of non-corroding bronze. Some interesting data regarding the bridge are given in the November bulletin of the Copper & Brass Research Association. The Brooklyn bridge across the East river, which has long been considered a marvelous product of engineering skill, is dwarfed by comparison with the new structure. The central span, over the water, will be 3240 feet long, and the approaches on each side will have a length of 1650 feet each. The two principal towers will be 840 feet high, or 48 feet taller than the Woolworth building, and each will have a base 200 by 400 feet. Traffic will pass over two decks, each 235 feet wide; the lower will provide for 12 standard-gauge railway tracks in addition to several hundred pipe-lines and conduits for electric wires. The upper deck will be wide enough to allow the simultaneous passage of 18 lines of automobiles, and will carry two street-railway tracks and two 15-ft. walks for pedestrians. The construction of the two huge trusses that form the suspension members of the bridge is remarkable. Each is composed of two cables spaced from 60 to 80 feet apart, vertically, with vertical panels and diagonal braces between to add rigidity. From the two suspension trusses,

vertical eyebar chains are suspended to support the double-decked roadway. Each of the four cables consists of three chains, the links of which are enormous steel eyebars, 60 to 70 feet long and 16 inches wide; the ends of the bars are connected by steel pins passing through the eyes. Each cable or cord of the suspension truss is composed of three chains, so that there are in all 12 chains spanning the river and sustaining the tremendous load that will be passing over the bridge almost continuously. Each of the four cables is to be enclosed in a gallery of bronze for protection against rain and moisture, which otherwise would attack the steel of which the links are composed. This gallery will completely encase the cord, but will be provided with necessary doors to permit inspection. The eyebars will be painted at the start, but, thanks to the protection afforded by the bronze cover, repainting will not be required for many years. The enclosing gallery will be 15 feet in diameter; although, of course, only a small part of this cross-sectional area is occupied by metal. The magnitude of the new bridge is emphasized by comparison with the four wire-ropes that support the Brooklyn bridge; they are 15 inches in diameter. The bronze obviously will add greatly to the sightliness of the structure, but that is not the reason why the cords are to be covered; the reason is that it is more economical to provide permanent protection than it would be to apply annual coats of paint. The same question of ultimate economy affected by the use of an alloy of copper arises in the erection of any permanent structure, even to the garage that one is building in his backyard.

ONE of the fruits of the President's Conference on Unemployment that promises to be of practical benefit, if it become law and be properly administered, is the bill introduced in Congress by Senator William S. Kenyon of Iowa, providing for the long-range planning of public improvements. No immediate results of consequence can be expected, but the soundness of the theory upon which the bill is based is undeniable. There are two kinds of industry: private and public. The first is conducted by individuals or corporations for private profit; the second is financed and executed for the benefit of the public. Mr. Otto T. Mallery, secretary of the Committee on Public Works of the Conference, presents statistics to show that the difference in wages paid in the United States in 1921 and 1920 is five billion dollars, which he assumes to be the "measure of acute unemployment". He estimates that 742 million dollars is the average annual amount expended for wages by governmental agencies in charge of public improvements. If, then, it were possible to increase the volume of public work threefold during periods of industrial depression there would be an excess expenditure of wages in the slack year amounting to 1484 millions over that of the average year. This will represent the potential usefulness of the proposed policy of regulating public work with a view to compensating for unemployment in private industry. Obviously, if the gross amount of work be not increased, the volume of public work must be diminished

during the period of general industrial activity. But history has shown that this activity always moves in cycles; to be specific, since 1900 the depressions have occurred at intervals of from 7 to 10 years. It seems practicable to expand and contract alternatively the volume of public improvements to accomplish the desired end. The bill provides, with respect to the national government, that the head of each executive department be authorized "to postpone the date of the commencement or retard the prosecution of such portions of the public works and projects within his jurisdiction as may be necessary, in order to prepare for and to prevent a further rise in the cyclical wave of industrial expansion and resulting business strain and over-extension and, within the appropriations therefor, to enter upon a maximum program of public works and projects as a preparation for and in order to counteract an impending period of industrial depression and unemployment". [What language these good people do use!] In order to inform Federal officials as well as the heads of State, county, and municipal governments, who are urged to co-operate in the work, the Bill provides that the Secretary of Commerce shall collect and compile regularly statistics bearing on business conditions and the industrial outlook. These, together with the Secretary's conclusions and recommendations, are to be published monthly as a supplement of the Current Survey of Business. In short, the plan is to use public industry as a fly-wheel to stabilize the unavoidable fluctuations of private industry.

IRELAND'S achievement of political autonomy is a happy event; it is of significance to this country because it marks the liberation of the United States from Irish politics, and gives assurance that the old quarrel between England and Ireland will cease to be a menace to the goodwill that should subsist between the English-speaking peoples on opposite sides of the Atlantic. In that goodwill lies the hope of peace for the world; for if we, the common inheritors of Magna Charta and Shakespeare, cannot live in amity, then the outlook will be dark indeed for civilization. It is fortunate also that the Spanish-American who was the least amenable to reason will be, as a newspaper reporter would say, "eliminated" from Irish politics, for his attempt to go back on the agreement made by the Sinn Féin representatives was an act of bad faith for which no excuse can be made. With De Valera will go, it is to be hoped, many of the extremists who derived support from funds distributed by the Third International and the Bolsheviks of eastern Europe. To Mr. Lloyd George is due great credit and the gratitude of all who desire peace and justice in this sad world. We hope that he may soon find it convenient to visit the United States, for he has many characteristics and personally engaging qualities that will make him welcome. Should he arrive at the close of the Washington Conference, if not before, he could, we feel sure, say some things that would stimulate the desire to establish good feeling among the nations, particularly between those which have the same language and the same liberal ideals.

Revision of the Mining Law

The numerous letters on this subject that have appeared in our columns during recent months indicate unmistakably that the mining community does not approve the proposed revision of the mining law. The subject has been discussed freely and at length by representatives of the various types of men engaged in mining. Their expressions of opinion indicate the belief that whereas the existing law has many faults, the proposed new one has fully as many, and that to put into effect so many radical changes at this time would only cause confusion. We join with our clientele in asking Congress to reject H. R. 7736, known as the 'United States Mining Act'.

In this issue we publish several communications on the subject. The first is from Mr. H. Foster Bain, Director of the U. S. Bureau of Mines. Mr. Bain explains the circumstances under which the revision was undertaken and the method adopted in selecting the committee that drafted the proposals for revision. He makes it clear that the sole purpose was to perform a public service by ascertaining the acknowledged defects in the existing law and by suggesting such remedial legislation as would correct them. Some of our prospector friends have assumed that the gentlemen who drafted the proposed regulations were persons unversed in mining and unfamiliar with the conditions for which they intended to legislate, more particularly with prospecting. This is a mistake, as we have stated previously. The committee consisted of mining engineers of wide experience, thoroughly familiar with every phase of mining, including the first discovery of ore and the locating of claims. It is true the members of the committee were consulting engineers of distinction and therefore such as are retained by the big companies, hence their point of view was that of the major operator rather than that of the prospector and small syndicate; this may have caused them to insert some of the clauses to which strong objection has been expressed by the minor operators. It is a pity that prospectors of small means were not represented on the committee, for it cannot be denied that such men are entitled to the kindest consideration of the mining engineer and of the Congressman. Moreover it is curious that after so much ventilation of the subject before the various technical societies and mining organizations it should have been impossible to draft a code that would be accepted and that would be defended by mining engineers. Nothing has been more marked in the public discussion of the question than the failure of members of our profession to come forward in its support. On the other hand, in private conversation with engineers and operators in various parts of the West we have found few inclined to welcome the new code. Most of the engineers withhold approval and most of the operators are frank in disapproval. Last week we published a copy of the adverse resolution passed by the Montana Mining Association, and the week before we published the text of a similar resolution by the Northwest Mining Association, at Spokane. A letter from the president and

secretary of the second association appears in our current issue. It refers, among other matters, to the difficulty of staking claims in conformity with cardinal lines and shows how much ground would have to be located in order to cover a vein on its dip under certain conditions. Here we may refer to the supposed chief benefit of the proposed enactment, namely, the abolition of the extra-lateral right. It is the objection to this and to the litigation caused by it that have provoked the cry for a revision of the law. As a matter of fact this defect in the law is now overcome in large measure by locating or purchasing more ground, and the new law furthers the same purpose by enlarging the area of the claims. The trouble is not so much with the law as with the vagaries of Nature; ore deposits have not the regularity of behavior assumed by legislators and the writers of textbooks; the eccentricities of vein-structure are beyond the discipline of Congress. In districts where apex claims have been located already, no revision of the law can prevent the complexities inseparable from changes in the strike and dip of veins or from the variations of shape and pitch in orebodies. We can state further that the average mine operator, much as he may fume at the 'apex law', would rather refer his troubles to the Courts* than to go to a bureaucratic official. He has said so to us. This may seem surprising, for many of the decisions of the Courts have been ridiculed and the litigation arising from the 'Law of the Apex' has provoked the anathemas of mining men; yet now that relief is offered they would "rather bear those ills they have than fly to others that they know not of". Some operators, as indicated by the report adopted by the Commercial Club of Salt Lake City, are willing to accept the abolition of the extra-lateral right, but consider it best to make no other change in the law. For ourselves, we believe that any benefit to result from repealing the law of the apex is belated, that the harm has been done, and that operators are now sufficiently on their guard against it, as is shown by the relatively few cases that come to trial, indicating a growing habit of compromise, and that the introduction of new claims without extra-lateral rights alongside those that have the apex privilege will only cause more confusion. The older mining districts are covered so completely with locations under the present law that any change will apply mainly to new districts, in which under existing conditions the operator will take the precaution of protecting himself by securing ground sufficient to cover the dip of his vein or lode. This means that the prospector has a better market for claims off the outcrop. Here we may mention the fact that the extra-lateral right is the only recognition that we have in our law of the severance of mineral rights from surface rights. This recognition is a good feature. What is needed most today is some way to hinder the passing of title to mineral land into the hands of persons who do not develop, but who wait for others to do so on land next to theirs, thereby obtaining an unearned increment in the value of their own idle property. Large tracts of the national domain have been alienated in this

way, by patent, preventing exploration by those who would be willing to incur the risk. Owing to the small tax levied on patented claims in neglected mining districts, it is possible to hold title at small cost. Apparently the remedy lies with local tax authorities. The subject of mineral-land laws is complex and difficult; the committee of engineers who undertook the revision made a sincere effort, for which they deserve the thanks of the mining community. It is a pity that they tried to do so much and that they grafted their new regulations onto the clauses of the old law, producing a verbal hotch-potch that would be a fruitful incubator of misunderstandings if enacted by Congress. The job was overdone; the resulting code is impracticable.

The Burma Enterprise

In our issue of November 29, 1919, we published a fairly complete history of the Burma mining enterprise, known at various periods by the names of the successive companies that have controlled it. At that time we stated that a new company was to be registered in India, for the purpose of obtaining further favor from the Indian government, including an extension of the mining leases, as well as to facilitate the erection and operation of a zinc-reduction plant in association with the celebrated Tata steel works in India. Various other expansions of the enterprise were described, notably a new concentrator and lead-smelting plant at Namtu, which is 15 miles from the mines at Bawdwin, in the Northern Shan States. The new company, still named the Burma Corporation, was registered in India on December 17, 1919. During 1920 the operating profit was £455,516, of which £246,770 survived as current profit. Besides, it was found necessary to raise more working capital by an issue of £1,000,000 in the form of 8% debentures. The temporary collapse of the metal markets in 1920 compelled the company to abandon most of its ambitious program of expansion, and early in 1921 it was decided to stop the construction of the zinc-plant in India, to discontinue the erection of the new lead-smelter, and to suspend the further development of the Namma coalfield. One unit of the concentrator is now in operation except for the flotation section, and the existing smelter at Namtu is being enlarged and improved with a view to an annual production of 45,000 tons of lead and 4,500,000 ounces of silver, requiring a daily output of 700 tons of ore. This relatively modest program is the result of consultation between Mr. R. G. Hall, whose engagement as resident manager expired in September of this year, and Mr. P. E. Marmion, elected a director a year ago and now appointed as manager in succession to Mr. Hall, together with Mr. A. T. W. Paine, another director, and Sir Trevorlyn Wynne, the chairman of the board, all of whom spent several months in Burma for the purpose of an exhaustive investigation. This enterprise has been the subject of many similar technical investigations and one may imagine that it must be tired of the repeated experience of being examined, appraised, and re-organized. It is now 17 years old, but has not paid a dividend.

Nevertheless it has received technical assistance from a splendid group of engineers, including Messrs. W. J. Loring, H. C. Hoover, R. Gilman Brown, Theodore J. Hoover, A. F. Keene, E. Heberlein, C. H. Macnutt, T. E. Mitchell, Lawrence Addicks, John A. Agnew, L. J. Mayreis, R. G. Hall, and E. P. Mathewson. The last mentioned is now on the ground. We give the names in chronological order as nearly as we can. Two conditions have been unfavorable to financial success. The first is the shortage of labor, which is particularly aggravated during the wet season, from May to November. The solution of the problem will be found in establishing colonies of natives from China and India in the immediate vicinity of the property and by encouraging the cultivation of individual plots of ground. The directors would be well advised to read the remarks of Mr. H. C. Perkins in our issue of May 19, 1917, on the training and use of native labor. Another unfortunate condition has arisen from the vagaries of rupee exchange. The expenses in Burma are paid in rupees; the rate of exchange has risen from 15 rupees to 7 rupees per pound sterling, so that the cost of labor, food, and local supplies has risen correspondingly. An ounce of silver buys no more in labor or in commodities than when the price of silver was half what it is now. As the lead is sold in India on a sterling basis, the company receives fewer rupees for it, notwithstanding a rise in the market price of the metal. These are some of the anomalies of exchange; when the company was registered in London it escaped from some of them. It looks therefore as if the Indian registration was a mistake. Meanwhile the ore-reserve is enormous and the potential wealth of the mine is unimpaired. The total ore available is estimated at 4,402,218 tons, averaging 23.9 ounces of silver, 25.7% lead, 17.9% zinc, and 1.2% copper. This represents a hundred million ounces of silver and a million tons of lead, together with three-quarters of a million tons of zinc. If Broken Hill did not compete it would be possible to sell the lead and zinc in Asia at a profit, but the mines of the Barrier can produce more cheaply. The capital invested is now equivalent to \$70,000,000. The Bawdwin is a great mine; it contains one of the biggest rich orebodies in the world, and the company has had, and now has, the benefit of the best technical advice; but the control has been divided and discordant, so that a consistent and sustained policy has been lacking. This defect is due partly to the disturbance of Indian finance and of economic conditions generally in consequence of the War. Although the company has paid no dividend, the £1 shares of the Burma Corporation, registered in London in 1913, have been quoted as high as £14. This means that the shares have served as counters in a big gamble. When the transfer to the Indian register was made the £1 shares were split into ten; these are now quoted at 6 shillings. This represents £3 as against £14 in January 1920. Thus apparently a great deal of money has been made by those who bought the shares when issued at 15 shillings in 1913, if sold anywhere near the top. More money is made on the bourse than at the bal, as a Cornishman might say.

DISCUSSION

Revision of the Mining Law

The Editor:

Sir—I have read with much interest the large number of letters that have appeared in the 'Press' since this discussion opened and am sure that they will prove helpful to the Committee of Congress which has the matter in charge. They reflect a deep and gratifying interest in the subject, although in part they also reflect misunderstandings, which must be due to failure to have read carefully the whole Bill or to understand what is now the law. A brief review of the conditions under which the draft under discussion was prepared may help to remove misapprehensions.

As is well known, there has been for many years dissatisfaction with the so-called mining law. This was the natural result of the fact that the United States never had a well considered mining code. What it has is a system of laws, interpreted by Department and court decisions, governing the manner of acquiring or occupying public lands containing minerals. These laws are fragmentary. They are a piece-work of individual statutes usually passed as a measure of expediency to meet a specific situation and only brought into any sort of working harmony by interpretations that have frequently been forced and even fanciful. Even such law as exists is scattered and difficult of access. The general land laws are now in process of codification and in time the laws governing mineral lands will be codified; if not as a result of the present effort, then as an incident to general codification by a body of lawyers. If the miners are to make their influence felt as to what is left out and what goes in, it will be necessary for them to decide among themselves what their experience dictates to be sound and wisely applicable to the future.

When in 1917 it became clear that Congress was in no mood to accede to a request that it appoint a committee or commission to study the actual operation of the mining law throughout the West and to recommend for or against changes that were being urged by individual groups, the matter was referred to the U. S. Bureau of Mines by the Chairman of the House Committee on Mines and Mining with a request for a report. The then Director of the Bureau appointed a committee from among its consulting engineers to consider the matter. He carefully chose this committee from among men not on the permanent staff but familiar with the problem and the actual operation of the laws. It was necessary to use men who could get together and consult, and the committee has

in this matter given time to public service that is worthy of the best thanks of the industry. Nor has it worked alone. By means of questionnaires, letters, and conferences the consensus of opinion has been obtained wherever possible from wide circles of mining men. The list of local engineering and mining societies consulted is a long one. Possibly a number of those who now see grave objections to some particular feature of the law as proposed have forgotten earlier appeals to them for expression of opinion.

If any progress was to be made it was clearly necessary for someone to draft in definite form and reduce to legal phraseology the various proposals that had back of them important opinion. This the committee has done, but neither its members, the Bureau of Mines, nor anyone else with whom I have come in contact has taken or would take the ground that the result is a proposal for a perfect law or that it may be, on the whole, wise to adopt every proposal made. This is not an attempt to thrust anything down the throat of anybody. It is an attempt to reduce to form for serious discussion various proposals that have been made. If they are good, they should be adopted; if they are bad, they should not. Whether they are good or bad should be determined by their estimated effect on the whole country and industry; not whether they be for the specific benefit of the large companies, the mining engineers, the lawyers, or even the prospector. The practical problem is what changes, if any, are necessary in order to smooth the way to discovery and development of such mineral resources as are not yet under exploitation.

In preparing its report the Committee first had a lawyer familiar with Land Office practice as relates to mineral lands bring together the scattered fragments of the law as it now is. The necessity for this is illustrated by the fact that one of your correspondents has soundly berated the Committee for proposing what is existing law as regards claim-staking in Alaska. Some of us might have welcomed a suggestion on the part of the Committee that the particular section indicated be omitted, but it is hardly in order to blame a new committee for what is now law. In fact, of the 25 sections in the proposed draft 18 are existing law save for some entirely minor and inconsequential change of a word or two to harmonize the whole.

In the remaining seven sections, certain new features are proposed. In general these are designed: (1) to do away with apex litigation as regards lode claims hereafter located by giving such new claims no extra-lateral

rights; (2) to open the way to development of large irregular bodies of ore such as the so-called porphyry cop-pers and especially deeply buried orebodies; (3) to force lands to patent; (4) to give permission to pay cash in lieu of assessment work.

As to the first-mentioned proposal, there is now little difference of opinion as to the time having come when it will be wise to change from the old system of extra-lateral rights. The number disposed to argue for the old system is distinctly in the minority, provided, as is most carefully done in the draft submitted, that existing rights be not abridged, and that the change to the vertical bound-ary system be made in such way as to introduce the mini-mum of confusion. The Committee, following the anal-ogy of the placer law long in use, proposed a 40-acre claim with permission to locate by 10-acre subdivisions, and, again following the existing placer law, proposed that where the land has been surveyed the location should be by land lines. This latter suggestion in particular has aroused vehement opposition. I cannot imagine that any one considers the particular suggestions vital, even though much good argument can be rallied to its sup-port. Since it seems clear that the miners see in this an undue hardship, it is unimportant. If the miners prefer to locate their claims without regard to land surveys and cardinal points there is no compelling reason for urging a contrary system. The miner will have to pay for patent surveys in every case, whereas under the system pro-posed he would in places have been relieved of this ex-pense, but apparently the prospectors in particular think it worth the difference and this is a matter in which they mainly are concerned. In your issue of November 19, Messrs. R. A. Dean and others discuss this matter and incidentally show that they are under a misapprehension. "Doubling the size of the mining claims" could not work hardship in the way suggested, since the proposed law allows location by lots of 10 acres, about equal to a half-claim as claims are now laid out, and permits assess-ment work to be done on the basis of acreage. As the law now stands, it is necessary to do \$100 worth of work on each claim, even though the actual ground not covered by previous locations is but a small fraction of a claim. Under the proposed law, the prospector would only do assessment work in proportion to the actual acreage he gets; under the present, he is required to do it by claims regardless of how much land he really gets. Substitution of a square claim with vertical boundaries is the essential reform. The size of the claim and how it be located is a minor detail.

The second object that the Committee had in mind in proposing changes was to open the way to simpler pro-cedure in acquirement of title to the large irregular ore-bodies, and especially those under a deep cap. Such title must be obtainable in the future if the industry is to prosper. As Mr. Dean and his friends say, "pros-pectors do not take up a claim unless there is an outcrop or some ore in sight", but there is much ore that does not outcrop and that accordingly the prospector is not equipped to find. There is nothing in the proposed new law to prevent any prospector from taking up any claim

on which he found an outcrop; why should he object to others using other means to find ore on other lands? It is proposed to open the way to do this by allowing a temporary possessory title to lands while the deep pros-pecting necessary to discovery is under way. Under cer-tain limitations also the results of drilling are to be recog-nized as constituting discovery. Some such system as this must be created if the deep orebodies are to be de-veloped honestly. No one familiar with the actual prac-tice at present can have any doubt that there is now no adequate legal system for acquiring title to lands in the amount and situation needed for financing the develop-ment of the larger orebodies where they do not outcrop. Title is acquired through subterfuge and elaborate legal fiction because it is the only way to do it. Men honestly trying to open such deposits have been put to large un-economical expense and laid open to blackmail because the public as a whole has been too ignorant or too lazy to create a simple honest way to the end desired. Let us do away with pretense and permit miners to be honest in legal matters as they are in life.

The suggestion that a limit be put to the time that land be held without discovery is certainly sound. Whether it is equally wise to set a time within which the claimant after discovery proceed to patent is a matter for debate, and especially what limit, if any, shall be established. The object of forcing claimants to go to patent is to con-vert public land into private land. So long as it is public land neither Federal nor State governments can force the land into use but when it once becomes private land the State may, if it choose, use its taxing power to compel the owner to mine or give up the land. This is a drastic suggestion. If any such procedure be adopted it should only be as a result of determination by the people in the State concerned. Forcing lands to patent gets the Fed-eral government out of the way and practically gives the people of the Western States authority which they now have only to a limited degree. Whether having it fully they would care to use it would be for them to decide. So far as the United States is concerned, provided there be an adequate system of registration of claims, it is a matter of indifference whether the claimant goes to patent or continues to do assessment work, since in either case the claimant's title is valid, where other provisions of the law have been fulfilled.

The fourth change proposed has given rise to odd mis-understandings. It is merely that when and where a claimant desires to do so he may pay cash to the Govern-ment in lieu of doing assessment work. It is permissive only, and anyone who prefers to hold his claim by doing assessment work would be fully entitled to do so. The object of the provision, which as it happens is also now before the Congress in another bill, is to open a way to avoid doing assessment work where it is clearly unneces-sary and wasteful. There are, for example, certain oil-shale claims in Colorado where the shale is so fully ex-posed that no additional test-pitting is necessary or de-sirable, and under present law there is, in this case, no other beneficial work to be done. The proposal is that the claimant may, if he choose, deposit money in lieu of as-

assessment with the Secretary of the Interior in a separate mineral development fund which must be spent by the Secretary for the benefit of the industry and as nearly as may be within the district in which the claims lie. The object is to permit such money to be used to build roads into the district or for some other general purpose equally beneficial.

The object of this certainly is not to create a vast fund "with which to operate nationalized mines", as suggested orally by one highly imaginative individual. If the object is not defined with sufficient clearness, the phraseology should be altered, but I can see no good reason for denying such a privilege to anyone who wants to use it. It is hardly to be supposed that there will be many checks for \$100 sent to the Secretary so long as it continues possible to contract assessment work at \$25 per claim.

I have sketched briefly herein the purpose back of the principal changes proposed and have tried to remove some of the misapprehensions that have arisen. Other objections have been urged, but they are mainly as to details, and a careful reading of the proposed law will, I think, remove most of them. In any event the matter is now before the House Committee on Mines and Mining and the Chairman of that Committee, Hon. M. E. Rhodes, has publicly expressed a wish that miners and others interested would give him the benefit of their advice in the matter. The whole matter is up before a friendly impartial committee, and those most concerned have a real opportunity to make their influence felt. Unless they do so, nothing will be done, and in due course the mining laws will be codified as a routine matter by a body of lawyers who may or may not have any real knowledge of the actual conditions under which mines are found, developed, financed, and operated.

H. FOSTER BAIN.

Washington, D. C., November 26.

The Editor:

Sir—H. R. 7736, entitled 'United States Mining Act', now in the House Committee on Mines and Mining, contains much that appears to threaten the mining industry; therefore, the undersigned respectfully beg your earnest attention to this protest against its passage.

While not admitting the need of any extensive revision of the present mining statutes, yet if such should be undertaken, and if our mineral resources are to be discovered and utilized, it is of paramount importance that the prospector be encouraged and protected to the utmost degree.

In the opinions of the members of this Association, H. R. 7736 not only fails to accomplish this protection and encouragement but it also actually introduces fresh complications and imposes new and unnecessary hardships, besides requiring that the usual gamut of the courts be run, whereas the existing laws have already been interpreted and are now well and generally understood.

Objection is specifically made to the following sections

and sub-sections of H. R. 7736, namely, Section 5-A, B, and C; Sections 6 and 7; and Section 13-A.

Section 5-A. Emphatic objection is made to this section for the following reasons: To require a prospector, or locator, to stake his claims in conformity with the cardinal lines of public-land surveys argues an ignorance of the practical difficulties that would be introduced by such a system. Principal among these may be mentioned, first, the usual difficulty in quickly locating public-survey corners; second, on unsurveyed land, the impracticability of locating claims by means of cardinal lines that shall even approximately agree with the definite lines of a final and subsequent public survey; third, and especially in rugged, broken country, covered with forests and brush perhaps, the impracticability of staking claims on veins that meander obliquely across a checker-board of cardinal lines so as to guarantee possession of valuable portions of those veins on their dip, particu-

SKETCH SHOWING METHOD OF LOCATING MINING CLAIMS UNDER PROPOSED LAW, COMPARED WITH PRESENT SYSTEM, AS INDICATED BY THE DOTTED LINES. TO POSSESS A VEIN STRIKING AS ABOVE AND HAVING A FLAT DIP, THE TRACTS MARKED WITH A CROSS WOULD BE NEEDED UNDER THIS NEW BILL.

larly when groups are limited to 160 acres. (See sketch attached.)

The prospector, or locator, is seldom or never a surveyor, nor can he be expected to employ one to aid him in the rush and excitement of staking new discoveries. Even under the present simple system of locating claims, the obstacles to be met are frequently many and harassing. In British Columbia, the square location may be made with one side parallel to the vein—not with sides running due north, south, east, and west—thereby greatly simplifying matters and guaranteeing possession of valuable portions of the vein on its dip.

As to subdivision B. of Section 5, this Association considers it to be one of the most vicious pieces of legislation ever proposed for the regulation of land-holdings.

While it is conceded that some well-guarded provision

should be made by which territory lacking visible signs of valuable minerals may be honestly prospected for suspected deposits, yet to throw land open to location for five years without discovery and with no more safeguards against fraud than are proposed in this sub-section, would most certainly result in the immediate plastering of vast acreages with blackmailing and obstructing locations, with the further net result of retarding mining development indefinitely.

Subdivision C, Section 5, is objectionable because it compels the filing of location notices and proofs of assessment work in the United States Land Office only. The same objection obtains in other sections of this bill wherein the Land Office is mentioned in this connection.

The locator of a mining claim should be permitted to file his notices and proofs of assessment work in the office of the County Recorder of the county in which his locations are made, as at present; but, it should be mandatory upon the Recorder to file, immediately, in the District Land Office, a copy of every such location in order to prevent the interferences that now arise.

U. S. Land Offices are often far distant from mineral locations, and the prospector, locator, or owner should not be compelled to travel those distances to consult the records.

Subdivision B, Section 6, is objectionable as regards the acceptance of a cash payment in lieu of actual assessment work on a claim.

This Association believes that too many claims lie undeveloped because of this privilege. It is also believed that lapsed claims should not be re-locatable by delinquent owners, or their representatives, for a period of one year from the date of lapse.

Section 7. Thirty-five or forty years ago, an abolishment of the extra-lateral right would have prevented considerable costly litigation and could have been accomplished without confusion; certainly it would have been of great benefit. But that was before most of the great camps of the United States had been discovered. Now, however, it is doubtful if there remains unprospected any considerable region, except Alaska, within which an important camp is likely to arise, or where the square location, bounded by vertical planes, could prove of any advantage whatsoever. On the contrary, in the re-location of lapsed claims in the midst of present locations it would not only prove useless but might well cause confusion.

Furthermore, the law of the apex is now so well understood by all mining men that locations are made with it in view and its hazard is taken with open eyes. Consequently, this Association is strongly opposed to any tampering with the well-established extra-lateral right at this late day, especially since no enactment can be retroactive.

Referring to Section 13-A, this Association objects to any change in the present method of obtaining mill-sites.

In conclusion, the undersigned is of the opinion that most mining men prefer evils that they know, if such there be, to those they know not of; moreover, that the mining industry as a whole will soon recover from the

present depression, and thrive better in future, if permitted to work out its many problems unhampered at this time by legislation of any sort.

NORTHWEST MINING ASSOCIATION,

By G. B. DENNIS, President.

F. C. BAILEY, Secretary.

Spokane, Washington, November 19.

The Editor:

Sir—In the discussions of the proposed new mining law, very few of the writers give any line-up of the kind of a code they prefer.

Why object to locating claims without a discovery? What show would a prospector have to acquire a claim, when a stampede is on, if he stopped to make a discovery before he located? While he was looking for mineral, others would post a notice of location, and rush off to record it, and he would have no recourse. If he found mineral, the others would say they saw it first.

It is a well-known fact that most of the best placer claims were staked by stampeders, who staked as near the discovery as they could, or took what was left, and never stopped to see if there was mineral on the claim; they rushed to the Recorder's office and filed their location notice. The same can be said of quartz claims.

The new law should change the name 'discovery monument' to 'location monument'.

How about a discovery before locating in a level desert country where the veins are covered from 10 to 100 feet with soil or wash? The surface would be classed as agricultural land. In such a district a bonanza silver strike was made, after 20 years or more prospecting, that will probably prove to be the best made in California. And there are other districts of the same description. How can such ground be prospected by a prospector if he is only able to sink one hole 10 feet in a year's time and is not allowed to locate until he finds mineral?

So long as a locator does his legal assessment work (which should not be too heavy) on his own claim or group of claims, he should be allowed to hold them, and when able, if he so desires, obtain a U. S. patent.

There should be a limit to the number of claims one could locate in a new district, but one should be allowed to hold and group all one can buy, or all one can stake in an old district, as it would help the owners of low-grade properties to dispose of them.

As to holding patented or unpatented claims and not working them: to force the owners of claims to operate would react upon the prospector, as he would only be able to sell a developed, or bonanza, claim.

It is a well-known fact that in mining one can easily get into a financial difficulty that may cause suspension of work for an indefinite time; and who would invest in a prospect or a partly developed mine if compelled to operate at a loss or lose their claims, when if allowed to bide their time they would be able to make a success of the venture and get their money back? In many mining districts there are mines or groups of claims that are not being worked. In some of them the owners have

them all tied up in that way, their money having been spent in development work, etc., but they lacked sufficient funds to put the property on a paying basis. Would it help prospecting if they are compelled to turn their claims back to the Government, and lose all they have invested? Not on your life! There are many gold properties that can be, and will be, operated when the time is right; so why confiscate them?

Let locations be made without discovery, and by all means let a patent be obtained at less expense to the claim owner.

W. K. WHITMORE.

Mojave, California, November 22.

A Definition of Engineering

The Editor:

Sir—In a recent conversation with several engineers a friendly argument arose as to the precise meaning of the title 'engineer'. Originally the name was applied to a man who made an engine or machine of any kind; later it was more generally used to signify the man who operated an engine—an engine-driver as he is called in most English-speaking countries outside the United States. However, the man whom we may call for the purpose of discussion a 'professional' engineer is a different person entirely from the engine-driver; it is to him that this discussion refers. Ours is an age of specialization. The arts comprehended by the term engineering are so diversified that there are hundreds of kinds of engineers, and in the accomplishment of any specific engineering feat or enterprise as many as a dozen specialists may participate. For this reason it is convenient to describe an engineer as one who engages in some specific branch of engineering and then attempt to define 'engineering', as being a more comprehensive term. I mean by this that the definition will embrace a wider range of work than is ordinarily undertaken by any individual engineer today. My suggestion, to which I invite criticism, is this:

"Engineering is the devising of plans and the contriving of means and methods for the creation of something having material value to mankind, by the utilization of machines, commodities, human labor, and the forces of nature".

I shall anticipate a few of the objections that may be raised to this definition and endeavor to answer them as well as I can. In the first place the definition is exceedingly comprehensive; a tailor, a farmer, or a cook might qualify as an engineer under the terms of it; but if they employ 'ingenuity' (derived from the same root as 'engineer') in accomplishing their work, can they be denied a place in the general classification of engineer? Why not a clothing or an agricultural or a culinary engineer as well as an automobile, a mining, or a chemical engineer; and why not much better than, for example, an efficiency engineer or a publicity engineer, or a sales engineer. The first term is ridiculous; the two others, at least, have arisen, I believe, from the fact that men who once engaged in engineering have undertaken work that

lacks the essentials of engineering, but are disinclined to abandon their former designation entirely. That is not to say that a first-class engineer may not be a good salesman; but when he is selling he is not doing engineering any more than he would be if he were playing golf. At the same time being a good engineer might make him both a better salesman and a better golfer. A good engineer must be efficient, just as a good accountant or stenographer must be efficient, but the principles of efficiency are the same everywhere, and there is little more justification for the title of 'efficiency engineer' than there is for those of 'efficiency accountant' or 'efficiency stenographer'. Engineer has become a name to conjure with! One of the problems in formulating a good definition is to qualify the terms in such a way as to exclude work that is not essentially engineering. How shall we eliminate the tailor?

Several of the men with whom I discussed the definition demur at the inclusion of the idea that human labor is one of the instruments of engineering. They hold that the engineer is concerned with inanimate things only. I am inclined to take the view that accomplishment is as essentially a part of engineering as is conception. Architecture, for instance, in the generally accepted sense, lacks one of the essentials of engineering. No tangible result can be obtained without some expenditure of human energy or labor. Suppose that our tailor measures a customer for a suit of clothes; decides upon the style of cut that will become him; selects the fabrics for the suit itself and for the lining; obtains the thread, the buttons, and the sewing-machine; even draws on paper the patterns for each piece. All this has been characteristically the work of a tailor; but if the particular tailor were to stop here he might just as well never have started, so far as the customer is concerned, because the customer himself cannot finish the job; and what he needs is a suit of clothes that is ready to wear. From a practical standpoint no tailoring has been accomplished. In the same way the essential part of engineering is the creation of some tangible thing of practical or material value, and that cannot be accomplished without the application of human labor.

Even if it be conceded for the sake of argument that the rôle of the engineer is only to plan and not to execute, he must still take human work into account, for according to our present standards an adequate 'design' includes a schedule of the approximate kind and number of men that will be required during consecutive periods in the construction so that progress in each branch of the work shall be made at the exact rate predetermined as being best. Definite plans must be made to co-ordinate labor.

Suppose that an engineer were to undertake the erection of two large earthen dams, one in Nevada, the other in the interior of China. The completed structures would be identical, the engineering problems would be entirely different, largely because in China the work would be done by coolies carrying the earth in baskets on their heads. The point that I wish to make is this: whereas

the engineer need not necessarily deal with the personalities of men as individuals, he cannot ignore their collective abilities, customs, and other attributes.

The all-round engineer need not be a 'welfare' worker; nor a diplomatic 'handler' of men; but human effort and labor is one of the important tools with which he works. He cannot leave it out of his calculations. If his enterprise is conducted in an isolated region, adequate provision for the lodging and boarding of the men who are to do the work is an essential element of the engineer's problem; some solution must be an integral part of his plan. A few engineers insist that the supplying of mere subsistence is not enough, and that the promotion of desirable 'human relations' is part of engineering. Frankly, I am not inclined to go so far as that.

In my definition I have implied that the object of engineering is to promote the material welfare of mankind. My friends protest, and say that the prime object of engineering effort is to earn money, first, for the employers or clients of the engineer; and, second, for the engineer himself. With this I am unable to agree. In the first place, unless the product of an engineering undertaking or enterprise is of material value to mankind, unless it promotes the general welfare of society, that undertaking or enterprise cannot earn money for its backers. Copper is converted into trolley-wires and iron into steel-rails; an electric railroad is a convenience and promotes the welfare of mankind, and for that reason copper and iron ores are mined from the earth. A steamship is a valuable asset to mankind because it permits the hauling of commodities and the travel of passengers between continents; for that reason steamships are constructed at great cost. Economic laws provide that financial compensation shall be accorded to those rendering a service, but if the production of copper and the building of ships did not render a definite material service to mankind, not any would be mined and none would be built. The welfare of mankind is fundamental; the financial profit is incidental.

Let us presume that for reasons of their own a firm of engineers volunteered to erect some useful public structure without profit to themselves; that is, they would merely be reimbursed for the actual cash outlay that they made. Would the structure be any less the result of engineering skill? would the work done be something else than engineering merely because no financial profit accrued to the engineers?

It seems to me that those who contend that the purpose of engineering is financial profit confuse two things, namely, the *purpose* of the undertaking and the *motive* of those who accomplish it. With the motives of individuals we are not concerned; they may or may not include financial gain, but if they do they must necessarily be predicated upon a material service to mankind. That is the *sine qua non* of an engineering project. There is no suggestion of altruism in this argument; it is based on purely practical considerations.

Considering for a moment the viewpoint of the individual engineer: it is necessary, sometimes inconveniently to be sure, that a man eat at comparatively frequent

intervals, and that he clothe himself if he desires to mingle unmolested with civilized people; a roof over his head adds greatly to his comfort, if it be not vitally essential, and for these reasons a great many engineers find it necessary to exchange their services for money. But I venture to suggest that, if they were given an annuity, sufficient to provide for their comfort, in lieu of any further salary or fee, a large majority of our really able engineers would continue to work as hard as ever with no thought of reward other than the hope of achieving something worth-while for the future welfare of their fellowmen. Do our statesmen, our railroad presidents, our preachers, our teachers, our writers, our composers, our scientists, our painters, our singers, our actors, our base-ball players work merely because of the money they get? Some do, many of the best do not; the same may be said of engineers. All this, however, is beside the point; the motives of individuals are diverse and complex; they do not count.

All *useful* occupations in the world necessarily promote the welfare of mankind—it may be the moral welfare, the mental welfare, the material welfare, or a combination of these. Engineering has as its object the advancement of our material welfare; in the definition, the more significant word is 'material', for that it is that distinguishes engineering from a large number of other kinds of endeavor.

As I have already stated, I offer this definition, tentatively, as a basis for discussion. I trust that others will feel free either to defend or to demolish it.

San Francisco, October 7.

A. B. PARSONS.

For some years one large copper-mining company has been experimenting with water-stoppers and now has more than 200 self-rotating machines of this type in use, says D. Harrington, of the U. S. Bureau of Mines. Two of its mines for a period of about a year prior to the shut-down in April 1921 had wholly discontinued the use of dry-stoppers. At present, in its only operating mine, wet-stoppers alone are being used. Three kinds of self-rotating wet-stoppers have been tried and all pronounced commercially successful. All are applicable to the drilling of any kind of ground in the district—hard to soft, solid to broken. This flexibility is due largely to the brake with which the machines are equipped. The self-rotating wet-stoppers drill nearly double (frequently more than double) the number of inches per minute drilled by dry-stoppers. Moreover, they prevent the formation of dust in the drill-hole, and the water used wets the surrounding rock and timber sufficiently to lay at least part of the dust in broken ore, on timbers, in chutes, and also materially decreases the temperature of hot places. While the first cost of the machines is nearly double that of dry-drills and the cost of upkeep more than double that of dry-drills, yet the company referred to, after a thorough trial extending over two years, has determined to adopt wet-stoppers as standard equipment in its mines. Progressive mine operators should see that wet-stoppers are given a thorough and a fair trial.

CRUSHING PLANT OF THE NEW CORNELIA COPPER COMPANY

Development of the Disc-Crusher and Leaching Practice

By A. W. Allen

In the preliminary tests in the United States on the ore from Chuquicamata, Chile, mechanical as well as chemical problems were investigated, an important subject being the secondary crushing of the material to a size that would ensure cheap and effective leaching. The original plans called for the use of 72-in. rolls for intermediate reduction from 5 in. (as it came from the McCully gyratory crusher) to $1\frac{1}{2}$ in. (for delivery to the 54 by 20-in. high-speed rolls). Tests made in New Jersey in the summer of 1913 caused a change of plan, 48-in. horizontal disc-crushers being substituted for the 72-in. rolls. It was found that the first cost was lower and the shipping weight was cut in half—an important consideration in view of the distance between the mine and the factory.

The second change in favor of disc-crushers was made after the first crushing-unit had been in operation in Chile, and when complete data were available. It was decided then to discard the high-speed rolls and to replace them with vertical disc-crushers, so that the ultimate as well as the penultimate reduction would be accomplished by these machines. At the time of my recent visit a mine output of about 13,000 tons per day was being reduced by means of eight 48-in. horizontal disc-crushers from over 3 to under $1\frac{1}{2}$ in., and by 24 vertical disc-crushers from $1\frac{1}{2}$ in. to a product that contained only about 12% plus 0.371 in. The machines are producing an ideal mixture for leaching; the change in favor of the disc-crusher has been due to an appreciation of its suitability and efficiency; personal likes and dislikes, bias or prejudice, have little weight in connection with decisions of an important nature in which first cost, operat-

ing cost, repair cost, renewal cost, and suitability of product are factors of importance. Therefore I was pleased to receive additional justification for an impression that I had held for many years that the disc-crusher operates on a principle that is unusually sound; the ore travels in the direction of an increasing discharge-area as it is being reduced in size, thus obviating the undesirable abrasion that takes place in the majority of crushing machines. If the operation of rolls or swing-jaw crushers for comparatively fine reduction be visualized, it will be understood that there is a great deal of compression among individual particles of the ore that may have been reduced already to a size that would justify discharge. But before such particles can reach the exit they are pressed between other, larger particles, with the result that an undesirable amount of abrasion and sliming ensues. This is an important consideration in leaching, where the avoidance of slime is desired, and where an undue production of slimed ore may make the process economically impossible.

The credit for the invention of the disc-crusher belongs to Edgar B. Symons, who built a 24-in. machine in 1908. The first unit developed structural weaknesses, and various modifications in design were proposed and adopted. The crusher was first used for the production of crushed gravel by a company in the State of Pennsylvania; its work was appreciated, and more machines were added. Designs were then made for several alternative sizes—18-, 36-, and 48-in. In 1913 the firm of Chalmers & Williams began to manufacture the crushers for the inventor, and later acquired the exclusive rights in the United States and in some foreign countries. The

original machines were made with a horizontal shaft, vertical discs, and a single driving pulley, as shown in Fig. 1. In this model, the eccentric bearing that carried the tail end of the inner shaft was stationary; the pulley was connected direct to the outer shaft, which communicated motion by friction to the inner shaft. The most important improvement was to adopt a second pulley, the hub of which was designed with a bearing on the inside for the tail end of the inner shaft. This is a distinctive feature of the machines now in use. The two pulleys are driven in opposite directions; the improvement in crushing is such that it is possible to revolve the main pulley at a much lower speed than formerly,

bearings, all of which are lubricated by means of circulating oil delivered by a pump (19); the stream of oil also lubricates the eccentric bearings (8) of the inner shaft. Adjustment shims are provided (30 to 35A) to regulate the size of the product or to compensate for the wear of the discs. The outer disc is held in position by the ring-nut (67); the inner disc is secured to the inner shaft, as shown in Fig. 3. A screw is used to lock and unlock a ratchet. In the illustration the inner disc is shown in place, but the ratchet set-screw is in the position in which it is possible to remove the ratchet-screw. By unscrewing the set-screw (68) the spring brings the ratchets together until they engage, so that

FIG. 1. THE ORIGINAL DISC-CRUSHER, KNOWN AS THE SYMONS SAND MACHINE

and to obtain greater crushing results and avoid excessive wear.

By referring to the accompanying drawing (Fig. 2), it will be seen that, at the extreme left, the pulley has an eccentric hub, by which a lateral motion is given to the inner shaft (28). This is connected with the inner disc (24), which is attached to a cast-iron habbitted ball behind a special ball-and-socket bearing. The main crushing load and the strain incidental thereto are sustained by the ball-and-socket bearing, for which a large surface is provided. Loose motion can be eliminated by tightening a nut (69). The outer shaft, which is revolved by a pulley (15), operates in the same direction and at the same speed as the inner shaft; it connects, by means of spider-bolts (41) and lock-nuts (77) with the outer disc (23), in the centre of which a delivery-spout (20) is placed. This shaft is supported by appropriate

bearings, all of which are lubricated by means of circulating oil delivered by a pump (19); the stream of oil also lubricates the eccentric bearings (8) of the inner shaft. Adjustment shims are provided (30 to 35A) to regulate the size of the product or to compensate for the wear of the discs. The outer disc is held in position by the ring-nut (67); the inner disc is secured to the inner shaft, as shown in Fig. 3. A screw is used to lock and unlock a ratchet. In the illustration the inner disc is shown in place, but the ratchet set-screw is in the position in which it is possible to remove the ratchet-screw. By unscrewing the set-screw (68) the spring brings the ratchets together until they engage, so that

the disc and ratchet-screw cannot turn when the crusher is in operation. The discs are given an even support by means of a bed of zinc, which is poured when molten into the space between the disc and the cast-iron ball, in the one case, and between the disc and the combination spider and plate in the other case.

'Minimum exit' in the following table is the distance between discs at the maximum opening. The figures of capacity for the 18-in. machine represent an average for ordinary hard rock. The higher of the two figures given for the 24-in. machine is invariably obtained in practice, and is often exceeded. With the two largest types the capacities given may be considered subnormal so far as rock of average hardness is concerned. Horse-power requirements never exceed the maximum given and are seldom more than an average of the two extremes mentioned. A higher consumption of power is

FIG. 2. SECTIONAL VIEW OF 36- AND 48-IN. SYMONS HORIZONTAL DISC-CRUSHER

noted sometimes where the rock crushed contains an excessive proportion of material that cakes and tends to choke the machine.

The two driving-pulleys run in opposite directions. The revolutions per minute of the driving and eccentric pulleys, respectively, are as follows: 18-in. crusher, 200 and 450; 24-in. crusher, 200 and 400; 36-in. crusher, 133 and 300; and 48-in. crusher, 100 and 250. Other details follow:

Size of disc, inches.....	18	24	36	48
Size of feed, inches.....	1½	2½	3½	6½
Minimum exit opening for best results, inches...	¾	1½	¾	1
Horse-power required ...	12 to 18	18 to 25	30 to 40	50 to 60
Capacity in tons per hour to pass a ring of:				
¾ in.....	5 to 8
1 in.....	8 to 10	12 to 15
1½ in.....	10 to 12	18 to 20	25 to 30
2 in.....	12 to 15	20 to 25	30 to 45	45 to 60
2½ in.....	25 to 30	45 to 60	60 to 80
3 in.....	50 to 65	80 to 100
3½ in.....	100 to 120

The disc-crusher is used almost entirely in the successive reduction of ore and rock to comparatively small sizes, and usually takes the discharge of swing-jaw crushers or gyratories. In comparison with gyratories for stage-reduction, it takes less head-room; in addition, it is asserted, a greater tonnage of material can be crushed per unit of power expended. This is due undoubtedly to the fact that the ore during crushing travels toward an increasing discharge-area, and not toward a decreasing one, as with the gyratory. As compared with jaw-crushers, the disc machine is handicapped by the fact that the possible range of reduction is considerably lower, but this is more than offset in most cases by the character of the product and the maintenance of a uniformity in this respect throughout the entire life of the wearing parts of the machine. The same favorable factor constitutes a point of superiority in the disc-crusher

FIG. 3. METHOD OF SECURING CRUSHING-DISC TO INNER SHAFT

over rolls. When using the latter the problems of corrugation and grooving are insistent, and the character of the product changes according to the condition of the shells.

The principle on which the vertical disc-crusher operates is essentially the same as that of the horizontal machine. It will be seen by referring to the accompanying illustration (Fig. 4) that the disc-shafts are vertical. The principal difference between the horizontal and vertical machines is that the size of the product from the latter is controlled by the minimum discharge-opening between the discs, whereas the product from the vertical-disc machine is gauged by the maximum opening between the discs. In this respect 'maximum' and 'minimum' are terms referring to the variations in distance

relatively fine grinding. For example, when crushing to $\frac{1}{4}$ in., the minimum exit is fixed at this dimension, the maximum opening being about $\frac{3}{4}$ inch.

The vertical machines are only made in the 48-in. size, but the upper disc can be changed to suit varying conditions. Thus, for example, for coarse crushing, an upper disc is made that permits the feeding of $4\frac{1}{2}$ -in. material, the product from which will all pass a $\frac{1}{2}$ -in. opening. By altering the adjustment, a 1-in. or a $1\frac{1}{4}$ -in. product can be reduced to $\frac{1}{4}$ in., or even smaller; with yet another type of disc, it can be reduced from $2\frac{1}{4}$ in. to $\frac{1}{8}$ in. The vertical machines are slightly more complicated than those of the alternative type, and more skill is required in making repairs and in effecting adjustments. The standard machines seldom require more than about 50

FIG. 4. STANDARD 48-IN. SYMONS VERTICAL DISC-CRUSHER

between the discs at opposite sides when the crusher is in operation, and does not refer in any way to possible changes that may be made in the apertures by the insertion of adjustment shims.

In the vertical machine the ore or other material to be crushed is fed through the centre of the upper disc and falls onto the lower disc; it is then thrown toward the periphery by centrifugal force, where it is crushed between them. The discs, as in the other type of machine, travel at similar speeds and in the same direction. It is pertinent to mention that the distribution of ore in the vertical machine is more perfect than with the other type, in which gravity interferes to a slight extent with the direction of flow of the crushed rock. In the vertical machine the material on the lower plate cannot escape until the two discs have come together one or more times; every particle must be reduced to the size of the minimum opening before it can be released. This facilitates

hp. At the Ajo plant of the New Cornelia Copper Co., a unit of three vertical disc-crushers reduces an average of 100 tons per hour. One crusher takes the discharge from a No. 8 gyratory, set to about $3\frac{1}{2}$ in., the product being passed over two stationary screens and the over-size is crushed in two vertical machines. The final product contains only about 22% on 3-mesh, and only 0.5% on a $\frac{1}{2}$ -in. round-hole screen. The ore is hard. During May 1920 the cost of crushing the product from the gyratories in the vertical machines to 3-mesh and finer, including power, repairs, labor, screening, and conveying, was 9 cents per ton. Further reductions are expected when the plant is again in operation and when 'normalcy' returns. Costs for such operations are generally misleading; they vary with the position of the property, the transportation facilities, and the size of the plant. The character of the rock in two different localities may differ to such an extent that the result from the

operation of duplicate plants may indicate a variation of 100% in the cost of crushing. In producing a relatively coarse product, a much greater tonnage can be handled with the same power and with the same steel consumption than would be the case of fine crushing.

The disc-crusher has come into prominence in the mining industry in connection with the beneficiation of low-grade copper ores by leaching. Two great plants, at Ajo, Arizona, and at Chuquibambilla, Chile, have adopted the machine entirely for the final reduction of their ores to a size suitable for leaching. The advantages of dry crushing previous to the application of wet methods of extraction are worthy of consideration. It obviates the separation of sand and gravel from slime and colloid—a separation that invariably occurs when water is used in quantity, as it is in all wet-crushing operations. It permits the economical leaching of the whole of the product of the mine in one operation, whereas, if the ore were crushed wet, it would be impossible to remove the excess water and at the same time to leave the slime evenly distributed throughout the mass. Not only would the slime escape proper treatment, but its presence in aggregations would interfere with the satisfactory and even leaching of the sand and the gravel. The alternative would be to isolate the slime by classification and to treat this separately. But slime treatment is expensive and usually inefficient; hence the overwhelming benefit of dry crushing, the even distribution of slime throughout the charge, and the leaching of the whole in large units. It is in connection with leaching that the disc-crushers have been favored, for the freedom of discharge facilitates the quick delivery of material that is crushed to a proper size, and prevents the sliming that too often occurs in other machines. The work at Ajo and at Chuquibambilla marks an era of bold advance in the metallurgy of copper; gold is a metal that, next to amalgamation, is being recovered by a leaching process. The dry crushing of ore and its subsequent leaching, as practised at the Ajo and Chuquibambilla plants, was developed by cyanide metallurgists many years ago. In India, in Rhodesia, and in South Dakota the gold ores were crushed to $\frac{1}{4}$ in. or so, and the entire mass was leached. In the American plant, the extraction was only 70%; but this result compares favorably with the extraction of 90% obtained at Chuquibambilla, when it is realized that the gold content of the South Dakota ore averaged only about 0.00035% of the mass in the first instance, whereas at Chuquibambilla the copper contents of the ore average about 2%. Further, recent mechanical advances, particularly in connection with crushing, have indicated the correct method of preparation of the ore for leaching. If the great copper plants today were obliged to rely on the crushing equipment available at the time of the operation of the Indian, Rhodesian, or American dry-crushing, direct-leaching plants, the results might well be doubted. It is probable, if modern ideas of crushing and leaching were now applied to material from many low-grade gold-ore deposits, that it might be found that an opening existed for profitable

exploitation by the utilization of the facilities that now exist for the efficient crushing, the uniform distribution of the dry material, and the leaching of the whole on a large scale. Although little is known about colloids, sufficient empirical knowledge has been gained to show that a preliminary baking treatment may serve to facilitate and cheapen preliminary crushing and will render the colloid slime innocuous. Here again there is a field for research in connection with leaching, which in some cases may be made feasible by the preliminary treatment of the ore with sufficient heat to minimize subsequent trouble from slime. If coarse gold be present in such ores it is obvious that the milling in water and the attendant trouble of the separation of the slime from the sand may be avoided by practising amalgamation after cyanidation. There are disadvantages, but they may well outweigh the advantages in such an exceptional case. In this, again, there has been little research. If gold be not dissolved by the cyanide, it is at least in excellent condition for amalgamation.

A third and equally important field for the application of scientific leaching is in connection with the treatment of the billions of tons of low-grade caliche and ripio on the Chilean pampa. Here again it has been demonstrated that disc-crushing of the material from the ripio dumps or from the salitreras, to a comparatively fine mesh, as in copper-leaching practice, or as in the early work of the cyanide metallurgists, is a satisfactory preliminary to an excellent extraction of the nitrate by the application of leaching principles that take into consideration the peculiar problems that have to be faced. Experience breeds assurance. The leaching tests on Chuquibambilla ores were commenced with 100-kilogramme lots; these were then increased to 2000 kg., and then to 14,000 kg. The results from the 14-ton experimental unit gave all the information that was needed for the design of the 10,000-ton plant. The results on a large scale duplicated the experimental results. Also in the case of the Ajo plant, the experimental work was commenced on a small scale; then 1-ton lots were treated, then 40-ton lots. With the information obtained a jump was made to a full-sized plant of 5000-ton units.

One of the great advantages of leaching is that an extraction obtained on one square foot of material can be duplicated with a million square feet, if necessary, provided that the depth is the same in each case, and the fundamental principles of leaching practice are observed. The work on the Chilean nitrate pampa was commenced with small tests; an oil-can was first used to determine comparative solubility of material crushed to various sizes. The second (single) test was made in a 5-in. pipe, about 10 ft. high, to prove the practicability of leaching through an economic depth of the crushed caliche. The third series of tests was made in a piece of round, iron boiler-plate, of about the same height as in the previous tests, 11 in. diam., and capable of holding about a quarter of a ton. The fourth series of tests was made in a square column, of riveted steel-plate; it held about half a ton and was about the same depth as the other columns. The

tinal test was made on 90 tons; and by this it was proved that identical results could be obtained, assuming the maintenance of the necessary conditions, whether the area of material leached was 1 square foot or 1000 sq. ft. It is all a question of the recognition of the fundamental principles of leaching, as developed by the cyanide metallurgists and the copper metallurgists, and as applied to a mixture of particles of widely differing size. Uneven distribution in the leaching-vat, for instance, will cause channeling and inefficient extraction. The fault lies not with the leaching process but comes as a result of a neglect to appreciate the essential requirements for uniform percolation. From the 90-ton unit to a 1000-ton or even a 5000-ton unit would have been a logical step in Chile; but it has been hard to convince the operators on the pampa that leaching can only be successful when fundamental principles are recognized. A great deal of money has been spent and much time has been wasted, for instance, in an endeavor to show that a homogeneous charge preparatory to leaching is unnecessary, that the advocacy of such is merely evidence of an adherence to theoretical refinements. Needless to say, the principle holds good, in spite of efforts to disprove it; the point is generally overlooked that such principles were enumerated in the first instance by those who had combined theory with practice, to the neglect of neither. After much insistence it is beginning to be realized that the mechanical distribution, by a system of main and cross-conveyors, constitutes the ideal method of filling a large vat with comparatively finely-crushed and dry material. Some of the 'practical' men of the pampa, the nitrate content of whose ripio dumps speaks for itself, hold out in favor of the tipping of carloads, or the delivery of caliche through a chute, at certain points in the vat, until piles of variable height are formed, down the sides of which the larger lumps slide; but a recognition of the absurdity of this proceeding is inevitable, although the process of enlightenment appears to be slow. Essential facts relating to the fundamental principles of leaching are, however, being recognized on the nitrate pampa. When the practicability of the efficient treatment of low-grade caliche on a large scale is realized, steps will be taken by the government of Chile to reduce the appalling expense, and wastage of national resources, that are now being incurred as a result of the selective mining, sorting, and treatment of high-grade caliche; for this practice involves the discard of large tonnages of nitrate-bearing material that should and could be treated at a profit. Further, the Government needs revenue, and this can best be obtained as a result of the exploitation of the nitrate deposits on an adequate scale and in an efficient manner. When this happens it is probable that the dry-crushed will be used extensively on the pampa, both for the penultimate as well as for the final crushing of the caliche. The adoption of the roll-crusher at any stage is not recommended; experience has shown that it is by no means an ideal machine for the comminution of a soft material for leaching, and for reasons already mentioned.

Success will also depend in large measure on the

methods adopted for elevating the crushed caliche and distributing it in the vat; the use of bucket elevators should be avoided; traveling-belt conveyors are preferable; in the majority of cases they can be used in place of bucket elevators. Further, the caliche coming to the plant as a result of average mining operations on the pampa is extraordinarily varied in physical character as well as in nitrate content. It is imperative that it be mixed thoroughly, and distributed evenly in the vat before leaching is commenced; the distribution is best effected also by traveling-belt conveyors. The enumeration of these details will indicate the progress in efficiency that has resulted since the early days of cyaniding a dry-crushed gold-silver ore.

As before mentioned, pampa operators are usually inclined to consider as unnecessary the rigid application of the fundamental principles involving the successful leaching of a mixed product; after a wholesale disregard of elementary reasoning it has been proved on a working scale that slipshod methods may yield a good actual recovery of nitrate. The Chilean nitrate industry has been accustomed to high losses in ripio after Shanks treatment; the amount of nitrate in the dumps that are scattered over the pampa offers conclusive proof of this assertion; but the times are changing rapidly, and it will soon be realized that a satisfactory recovery from a low-grade caliche will ensure the prosperity as well as the continued existence of the industry; and thoughtful technicians who are able to appreciate the fundamentals of efficient leaching will insist that, when percolation has been commenced, the treatment should be carried to a logical conclusion—until a high proportion of the desired soluble has been removed. A disregard of mechanical and physical considerations will make this impossible.

THE minimum temperature required for the roasting of zinc-blende is about 600°C. The most economical temperature to use on low-grade concentrate is between 650 and 725°C. In preparing ore for leaching with sulphuric acid the main object is to obtain as nearly as possible a dead-roast with the minimum formation of ferrite, which is insoluble in dilute sulphuric acid of the strength usually found convenient in an electrolytic plant, according to a paper read by J. T. Ellsworth. Either the oxide- or the sulphate-roast may be used. The furnaces ordinarily used at present are six- or seven-hearth McDougall or Wedge type, fired with coal or oil. These furnaces are best adapted to the sulphate-roast, which consists in exposing the concentrate for 15 hours to a temperature of about 650°C. This roast is necessary when the material treated is high in iron, say around 20%, on account of the more rapid formation of ferrite at higher temperatures. If the iron is around 10% the oxide-roast with a temperature of 700 to 725°C. is preferable, but the time should be lengthened to at least 24 hours in order to lower the proportion of sulphide sufficiently to avoid its concentration and re-handling from the leach residue, which is quite often necessary with the sulphate-roast.

The California Rand Silver Mine—II

Geology, Development, and Mining

By Arthur B. Parsons

The preceding article recounted the story of the discovery, in April 1919, of this remarkable bonanza of silver ore in the old gold-producing district of Randsburg, near the eastern border of Kern county in California, and of the production within 30 months of silver-gold ore having a gross value of 2½ million dollars, with the payment of nearly a million dollars in dividends. In this article I shall point out, among other things, some of the interesting geological features of the deposit as they have been revealed by the operations of the California Rand company and sundry lessees, as well as by the work of the Randsburg Silver Mining Co., which owns the Coyote claim, adjoining Uranium No. 5, as indicated on the accompanying map of the district (see Fig. 1). A 500-ft. shaft, from the bottom of which cross-cuts have been run both south-east and south-west, has proved the existence of silver-bearing veins underlying the Coyote claim.

GEOLOGY OF THE DISTRICT. The country-rock in the productive part of the Randsburg district, including both the older gold 'zone' and the newly discovered silver 'zone', is a highly altered schist, which is classified as "a mica-albite schist of probable sedimentary origin" by Frank L. Hess, who made an examination and report on the quadrangle for the U. S. Geological Survey in 1909. An intrusion of granite cuts across the Rand mountains south of Randsburg; it is roughly crescent-shaped, and is several miles long; in places, it is half a mile wide. The Yellow Aster mine, which is credited with a production of \$9,000,000 in gold, is situated at the intersection of this granitic intrusion with the axis of the Rand range of mountains. The ore deposits are closely associated with the granite and with numerous adjacent granite-porphry dikes that, according to Hess, are "probably connected to it". The intrusion of granite can be traced across the country in a south-easterly direction and can be identified immediately north of the California Rand workings.

Hess describes three different types of ore in the schist-granite area; they are: (1) fault-lodes or deposits along faults in crushed schist and granite; (2) stockworks in granite; (3) fissure-veins, containing quartz in varying quantity. Although the rich silver-bearing ore had not been discovered at the time he visited the district, the physical characteristics of the silver deposits are not dissimilar to those which Hess describes, except that, in the silver zone, ore of the stockwork type is found in the altered schist rather than in a rock that can be identified distinctly as granite. In fact, no silver ore has up to

this time been found north of the contact of the schist with the regional intrusion of granite. The summary of the deductions that Mr. Hess made regarding the genesis of the ore is interesting. He says: "It seems probable that, after the intrusion of the granite and the granite-porphry dikes, a large amount of hot water was squeezed from the granite while it was cooling. The water carried silica, gold, silver, iron, sulphur, arsenic, lime, tungsten, and a little tellurium and titanium in solution, and flowed along the faults and shearing planes and through the broken granite. The minerals were deposited wherever chemical reactions took place". All the geologists who have studied the district appear to agree that the large crescent-shaped intrusion of granite was undoubtedly the primary source of the minerals that were deposited in fractures traversing the complex of schist and granite, to form the gold-bearing deposits. These start from the Yellow Aster and are found at irregular intervals in the contact zone as far east as the Juanita claim. It will be recalled that the early work on the Juanita consisted of prospecting for gold; and that the original discovery of silver ore was made in the district some years later near the south-eastern end of the claim.

THE CALIFORNIA RAND MINE. The lode on which the Juanita claim was located is at the contact between the schist and the granite of the regional intrusion. This contact strikes south-easterly and dips at a low angle (about 30°) to the north; the side-lines of the Juanita claim are approximately parallel to the strike of the contact. A second intrusion is the silicious dike—called porphyry by some geologists—that strikes approximately at right angles to the schist-granite contact, and which determined the direction of the side-lines of the Uranium claims at the time they were originally located. This dike can be seen outcropping boldly on the hill south-west of the mine. The outcrop appears to mark the foot-wall of the intrusive mass; it can be traced through Uranium No. 1 and Uranium No. 2 to a point about 100 ft. north-west of the company's No. 1 shaft, but it disappears as soon as the granite area is reached, presumably because the intrusion could not penetrate the granite, which is regarded as being older. A 105-ft. shaft, sunk 330 ft. north of No. 1 shaft, and near the north end-line of Uranium No. 2 was in granitic rock for 60 ft., at which depth it entered the schist. A north-west cross-cut in the schist passed through a hard formation that presumably is the east-west dike. If this be the case, the dike is about 60 ft. wide at this point.

One hypothesis for the deposition of the ore is based on the theory that the granite shattered the adjacent schist and formed the north-south fractures that have now become the silver-bearing veins. The subsequent intrusion of the silicious dike re-opened these fractures and probably introduced the silver-bearing solutions. The fissured area near the schist-granite contact was particularly receptive not only because of its physical condition, but perhaps because of its chemical characteristics;

takes an easterly course through Uranium No. 2 and No. 5. No. 1 shaft was started at the discovery-point and followed a wide lode, with a well-defined foot-wall, commonly known as the 'shaft fracture'. A drift on the second level of this fracture has been followed for a total distance of 510 ft., including some work from the 105-ft. shaft mentioned above.

The ore at the surface was oxidized, with flakes and bunches of hornsilver. A peculiarity was the alterna-

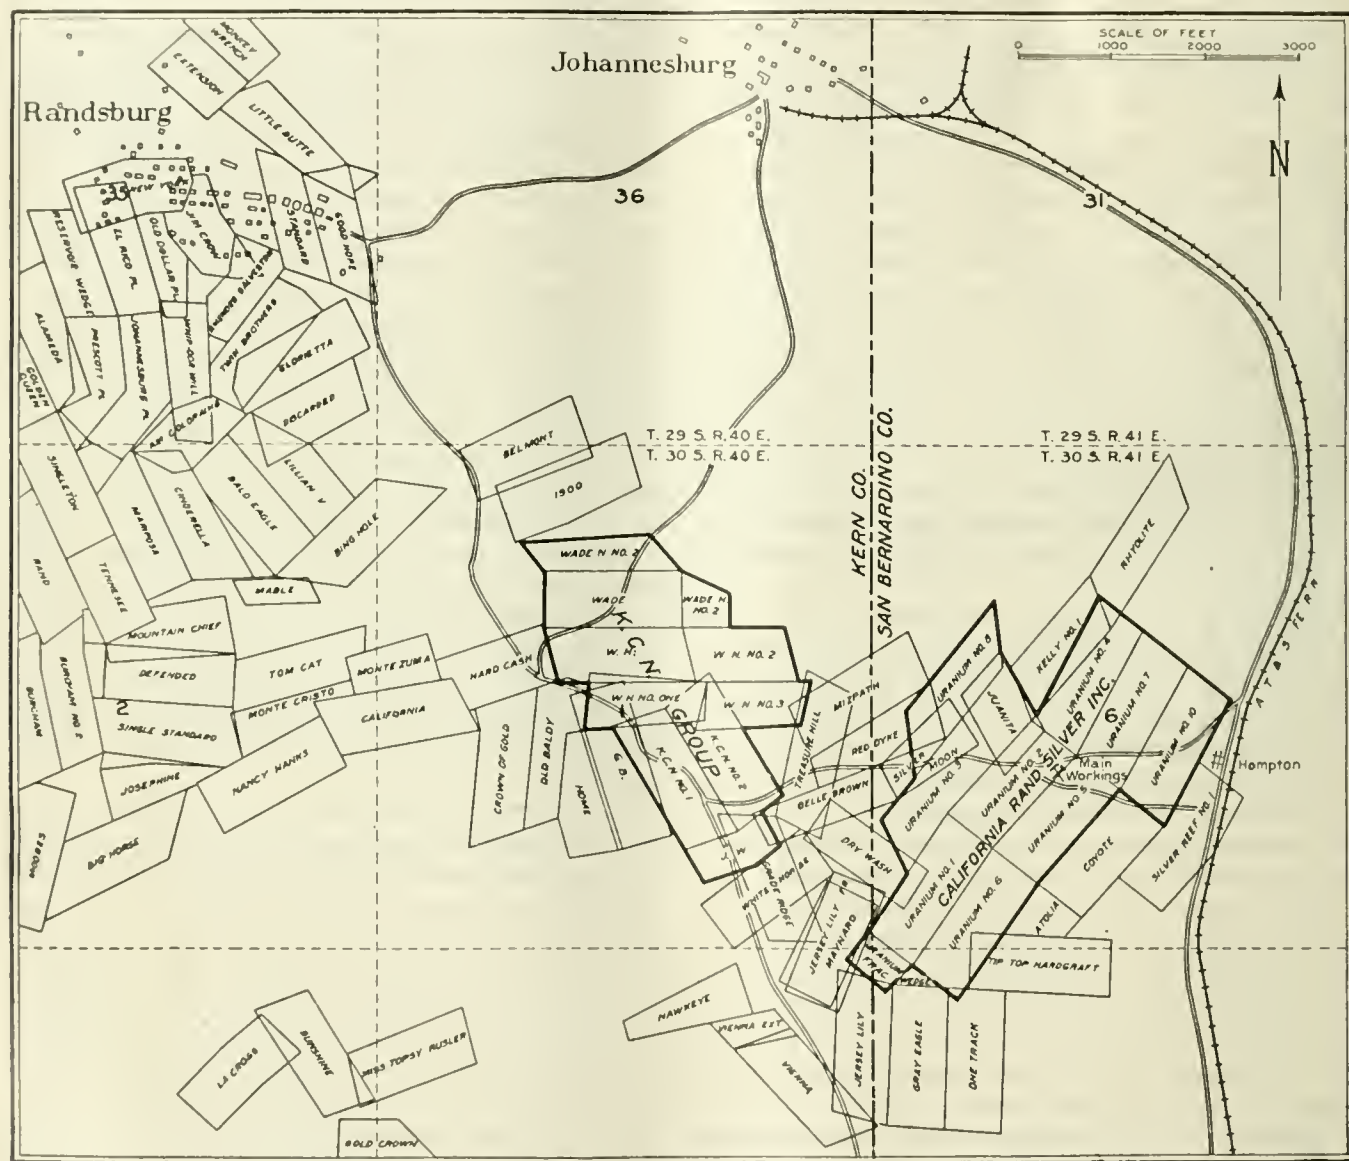

FIG. 1. CLAIM-MAP OF THE RANDSBURG DISTRICT

that is, the minerals deposited at the time of the intrusion of the granite may later have reacted chemically to stimulate the precipitation of the minerals that formed the rich silver ore. At any rate the silicious dike seems to be the dividing line between the gold and the silver zones of the district, even though it may develop that some other intrusion, which subsequently may be found, brought the enriching solutions.

The point of discovery was 120 ft. east of the foot-wall of the dike, on a line that represents the prolongation of the Juanita contact-vein. The vein itself cannot be traced beyond the dike, although the contact swings and

tion of thin layers of hard and soft material, the soft being far richer than the hard. These layers dipped only from 5° to 15°, to the east, and, as progress was made in sinking, there was constant speculation as to whether each successive lean layer would be underlain by a rich one. The pessimists were sure that the deposit was only a freak, and that after a few lenses near the surface had been mined the bottom would be reached, and it would remain only to follow the layers horizontally to the limits of the orebody. For the first 50 ft. the 'shaft' was a pit approximately 18 by 22 ft. in lateral dimensions, dipping to the east about 78°. As I mentioned in the

previous article, every pound taken from this pit was shipped as ore. A simple but reasonable explanation of this 'bedded' deposit is that the 'beds' are really flat veins formed by the filling of fractures in the schist, and that the coincidental impregnation of the intervening layers with silver-bearing solution made the lower-grade 'beds'. Or, it may be that some of the layers of schist were more porous or more soluble than others and that the ore-carrying solutions, accordingly, deposited more of their burden in them. The oxidized ore is doubtless enriched by secondary precipitation from descending

the vein except the single outcrop that formed the discovery vein. Had erosion stopped a short time—geologically speaking—before it did, it is probable that even the luck of Williams and Nossor would have failed to find the ore. It is this 'mud wall' that makes it necessary to sink on the Coyote claim and the others lying to the east, in order to prospect. The presumption is that the wall extends indefinitely, though fortunately it appears to flatten, so that the distance necessary to sink in order to pass through it does not increase rapidly.

Fig. 2 also shows the Grady shaft and the boundaries of Grady's block of ground from which he expects to take more than \$1,250,000 before his lease expires. It appears that if Grady had selected a spot 20 ft. farther east for his shaft he would have had to sink to about 430 ft. before finding ore instead of cutting it at 200 ft. The chief interest attaching to Grady's mining, however, is the fact that he selected his lease-block in a direction that to everyone else appeared to be entirely off the trend of the ore. A dozen leases were granted in Uranium No. 1, in No. 2, and in No. 4, but no one except Grady considered No. 5 as being worth while. Grady, it appears, was more impressed than others by the fact that rich ore at the point of discovery was near the juncture of the Juanita vein with the north-south dike. He took samples along the surface in the direction of the northerly prolongation of the dike, but failed to find indications of silver, and therefore abandoned the idea of taking a lease in that direction. There remained the possibility that the Juanita vein might have some remote connection with the orebodies. He could not find the contact between the schist and the granite on Uranium No. 5, and accordingly he projected the line of the Juanita vein across Uranium No. 2 and selected the site for his shaft on this projection. In view of the fact that his lease contained an apex clause, it is hard to see why he wanted to be so close to company ground in the direction of the dip of the veins, unless he failed to appreciate the significance of the apex provision. The story of the threatened litigation and the compromise was told in my earlier article.

It should be remembered that at the time the compromise was made, development in the company workings had advanced only to the fourth level; accordingly, no evidence existed to show that the main vein made a junction with Grady's vein. Although the large branches of the main vein dipped easterly, it seemed clear that the Grady discovery-vein dipped in the opposite direction and that a segment of its apex lay within the lease-block, which originally extended 175 ft. farther east than is indicated in the drawing. The latter represents the smaller block as agreed upon at the time the controversy was settled. If the case had been decided on its merits it seems probable that Grady could have established right to the ore in the branch vein between the points where his shaft first cut it, just below the mud wall, and the point of intersection with the main vein. An interesting question would then arise as to what further ore, if any, would rightfully be his. Could he follow the vertical portion of the vein below the junction? or could he prove

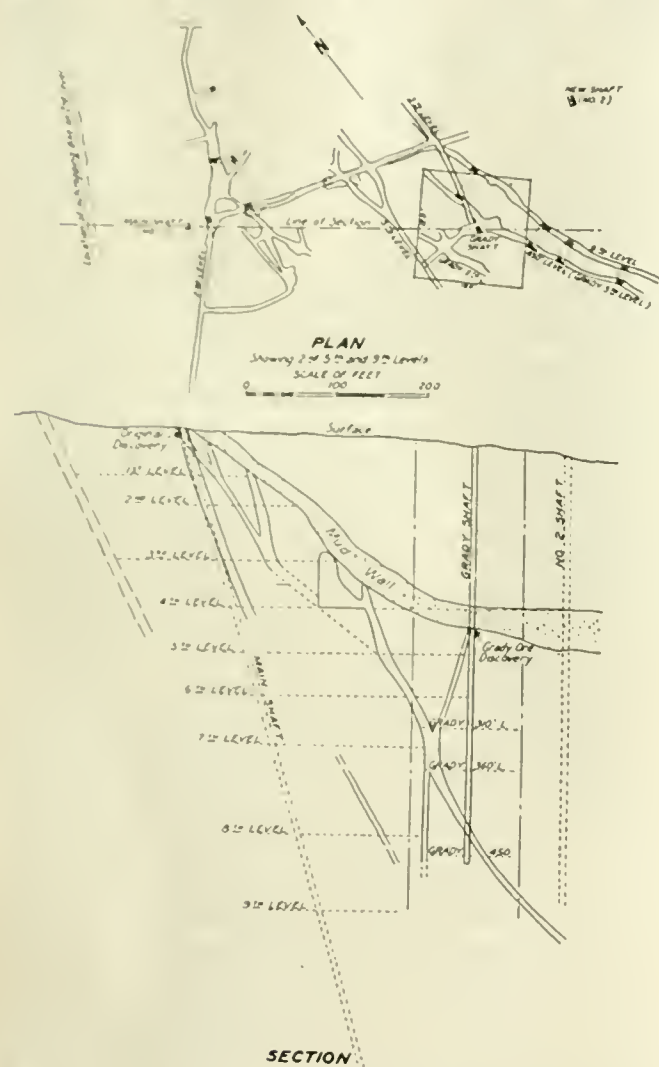

FIG. 2. SHOWING PART OF THE WORKINGS OF THE CALIFORNIA RAND MINE. THE 2ND, 5TH, AND 9TH LEVELS ONLY APPEAR ON THE PLAN.

silver-bearing solutions. Such ore is not found below the 150-ft. level.

The foot-wall of the dike has been reached by cross-cuts on the first and third levels as indicated on the accompanying drawing, Fig. 2. This section is taken through the collars of the main No. 1 shaft and the shaft on the Grady lease, so that No. 1 shaft, being off the plane of the section, does not appear to coincide with the dip of the shaft-fracture.

This section also shows the 'mud wall'—the foot-wall of a fault-zone—that has decapitated every branch of

that the wider easterly dipping portion of the vein, below the junction, was part of his vein? The answer to these questions would involve a detailed study of the geologic and mineralogic characteristics of the veins and of the ore. Such a study has never been made, but the problem is interesting nevertheless. Still another possibility existed: he might have established the contention that the Juanita contact vein was the true lode and that the north-south veins were branches or spurs from it. If Grady could have done this, the side-lines of Uranium No. 2 and No. 5 would have become end-lines and he could then have mined the ore between the common side-line and his other parallel line. Such a contention, however, would be exceedingly far-fetched in view of the mining done in the workings both of the company and of the lessee. On the 50-ft. level the shaft-fracture, striking N. 30° E., has produced shipping ore for a distance of 220 ft. On the lower levels the shoots of sulphide ore have been developed for more than 200 ft. in a general north-south direction, and the veins have been followed for greater distances, although they do not contain ore throughout their length. The existence of north-south veins of distinct identity must be conceded. Incidentally, I may mention the fact that one of the directors of the Randsburg Silver Mining Co. intimated to me that a contention based on the identification of a main east-west lode might be advanced by his company in an effort to make good its claim to ore that underlies its Coyote claim but that is found in north-south veins that presumably apex in Uranium No. 5. In a recent letter to the stockholders of the California Rand company, Alfred Harrell, the president, says: "The one disquieting feature in connection with our property grows out of activities in the immediate neighborhood of our mine". He urges that "our orebodies must be protected against encroachment".

The Randsburg Silver Mining Co. sank its shaft on the Coyote claim directly in line with the California Rand No. 1 and Grady shafts, or on the projection of the Juanita dike. At 468 ft. a silver-bearing vein was cut, according to reports, but not prospected. At 500 ft. a cross-cut was driven easterly and "278 ft. east of the common side-line [between the California Rand and Randsburg Silver mines] we encountered and are opening up an 8-ft. vein, the direction of its course so far as developed now runs apparently lengthwise through the Coyote and dips toward the east at a pitch of 50° to 60° where encountered, to almost perpendicular in the end of the south drift, now 120 ft. long, on September 17, thus apexing within our claim beyond any question". This is quoted from a circular the purpose of which was to market 50,000 shares of the Randsburg Silver company's stock. However, the company has decided not to ship any ore for the present—whether because it has little to ship, or because it is not sure of the "apexing within our claim without any question" is a puzzle. It is possible that the vein cut in the Coyote, even if it does apex in Uranium No. 5, is not a branch of the main vein but an independent one. In that event it may curve

around on its strike so as to leave Uranium No. 5 through its east side-line, in which event the Randsburg Silver company would be entitled to a segment of the vein.

However, the ground intervening between the California Rand workings and the side-line between the Coyote and Uranium No. 5 claims has not yet been explored or developed; when this is done additional light will be thrown on the structural geology, and the questions of apex and ownership of the ore may settle themselves; or it may be that further information will complicate the problems and the outcome will be litigation. A better solution would be a compromise involving the absorption of the Randsburg Silver company by the California Rand company. I do not know that the latter corporation has any desire to acquire the Coyote claim, but if orebodies of any size are developed they could be more advantageously worked by the California Rand than by an independent company.

DEVELOPMENT OF THE MINE. The drawing that shows the section through the shafts indicates the small interval between the levels, the average, down to the seventh, being exactly 50 ft. Two reasons for this are: (1) the fact that development work has never been carried far ahead of mining operations for current production, and (2) the policy of following the ore closely. The high-grade veins split and branch, pinch and widen, both on the strike and on the dip; they are cut by sundry cross-fractures, the intersections usually marking the position of richer ore. For this reason it was desirable to keep close to the ore in order that none might be overlooked, or that time might not be wasted in cross-cutting and drifting in search of the shoots. The running of levels at frequent intervals was pursuant to this policy. The workings on the 90- and 150-ft. levels reached the limits of the shipping ore at points disappointingly near the shaft; accordingly, the development of the third level at 200 was undertaken with some apprehension. The results, however, were reassuring. Ore was taken from long stopes on each of the two vein-systems, one of which strikes nearly north and south, and the other 10° or 15° west of north. On the lower levels connection is made with the Grady workings where the junction of two veins, on both their dip and their strike, has made an ore-shoot 27 ft. wide; and on each of the succeeding levels the development is satisfactory.

In addition to the high-grade shoots that have been partly stoped above the seventh level much low-grade ore has been exposed. The tonnage actually blocked out is not large, but the drifting and stoping to produce ore, together with some work done primarily for development, have shown that 100,000 tons of \$20 ore is reasonably assured, above the ninth level.

At points where there is no definite quartz vein of rich ore the schist is frequently streaked with small veinlets of sulphide minerals, caused by deposition in a network of small fractures running in all directions. Much of this material will be mill-ore; the line of demarcation between ore and waste will be determined by

assay. In some parts of the mine a single rich vein is too narrow to stope for shipping ore but can be removed with some adjacent rock and sent to the mill.

CHARACTER OF THE ORE. The ore in the oxidized horizon contains chlorides, oxides, and sulphides in flakes or splotches, together with some bromides and iodides, the gangue being relatively pure quartz. Below the third level, at 150 ft., the ore is exclusively sulphidic, the silver-bearing minerals being argentite, pyrargyrite, proustite, and stephanite. An interesting feature is that, in the richest ore, arsenic rather than antimony seems invariably to be the essential constituent. This might be interpreted as indicating that much of the antimony is in the form of stibnite or other minerals that are not silver-bearing. The gold is believed to be associated with pyrite. In addition to ore in which the silver-bearing minerals in irregular patches seem to be enclosed in the silicified schist with an absence of definite walls, the sulphide horizon also contains well-defined veins composed of compact quartz in which the silver minerals are uniformly disseminated, thereby indicating "concurrent deposition", according to Morris B. Parker, who made a number of geological examinations of the mine for the California Rand company. He considers this to be "primary ore, that has undergone no change since original deposition occurred". On the 250-ft. level, ore of this character assayed from 200 to 300 oz. in a vein 6 to 12 in. wide. This is interpreted by Mr. Parker as proving that the high-grade ore is not confined to a horizon near the surface, where secondary enrichment by re-deposition has concentrated the silver.

MIXING. The rapidity with which mining operations were commenced in 1919 was due in part to sundry unusually advantageous conditions. The transmission line of the Southern Sierra Power Co., connecting the generating station at Bishop with the Imperial Valley, passed within less than half a mile of the mine; a pipe-line that was originally laid to supply water to the Osdick mill passed directly through the California Rand property; tracks of the Santa Fe railroad company were only three-quarters of a mile distant; and a good highway was ready for traffic to Randsburg or to the railroad-siding. As soon as the shaft was well started, the partners purchased an electrically-driven hoist, built by the Colorado Iron Works company and equipped with a 50-hp. General Electric motor. A little later two 12 by 10-in. Ingersoll-Rand compressors with appropriate motors were installed and a Champion blower with an eight-inch air-pipe was provided to assist ventilation. Additional equipment has recently been purchased for the compressor plant, as the requirements have increased.

There is nothing novel in the methods of mining. The schist lies nearly horizontal and the ground holds remarkably well without timbers. At the point in the Grady lease where the big orebody has been mined the walls of a huge cavern stand without any supporting timber. Overhand breast-stopping, with a few stulls to provide staging from which to drill, has been used ex-

clusively until recently. J. M. Fox, the new mine superintendent, has started a shrinkage stope above the sixth level. The prime object is to provide a reserve of broken ore from which to draw if all the faces happen to 'pinch' coincidentally.

In anticipation of the completion of the flotation plant, which is now in the course of construction, a new two-compartment vertical shaft was started in April 1921. At the time of writing it has reached the depth of 500 ft. and is being connected with the workings, ready to serve as the main exit for ore about the first of next year, soon after the mill is in operation. The new shaft is north and a little east of the Grady shaft and is just above the site of the mill, which was selected so that the plant would be conveniently situated to receive ore directly from the shaft. The primary crusher is to be fed directly from the mine-ore bin; the broken rock will be carried to the mill structure proper on an inclined belt-conveyor. My concluding article will describe the tests conducted to determine the most advantageous method of treating the ore, and sundry features of the proposed flow-sheet.

(To be Concluded)

WHEN war science learned how to destroy thousands at a stroke, to ruin whole cities in the space of a breath drawn in the middle of the night, peace seemed more and more desirable, says Francis P. Garvan, in an address delivered before the Society of Chemical Industry and the American Chemical Society. "As the researchers in the sciences contributed in ever-increasing frightfulness to the power and long-distance application of war weapons, destroying all the romance of industrial combat and nullifying individual courage, men began to see increasing merit in the dreams of those who would abolish war utterly and who would police the evil doers of the earth as such are policed in our cities. When the creative chemist showed military commanders how an opposing host could be stricken from life on the wings of the wind, laid horribly in death by a vapor as noiseless as the pinions of Azrael; how life could be expelled from great cities by a death dew of acids sprinkled from airplanes, peace became a boon to be prayed for in utter sincerity. Hypocrisy, smiling at gunpowder, blanched before phosgene gas. I do not say that the spread of education and gradual refinement of the spiritual side of man has not played a part in the growth of the ideal, nor that the operation of pure reason has not contributed to the vitality of the desire. I do maintain, with history at my back, that successive inventions of horribly destructive weapons and successive demonstrations of the magnified and unpreventable ruin and misery wrought by one new weapon after another, have been successive shocks to man's long-time notions about the indispensability of war. There was a time when he said that war could not be prevented. Then he began to say that it was disagreeable on the whole, that it ought to be prevented. Now he is beginning to see that it is so frightful that it must be prevented."

The Lead-Acetate Tartaric-Acid Method of Assaying Cyanide Solutions

By F. Borzynski

The lead-acetate method of assaying solutions for gold and silver is generally used by assayers. With comparatively pure cyanide solutions the method gives good results, but trouble is frequently encountered when the solutions contain impurities or are more than slightly alkaline. The lead sponge obtained under those conditions is often friable and resembles lead powder more than lead sponge. The separation of the powdered sponge from the solution is slow and tiresome work; besides, there is the danger of erroneous results due to the loss of particles of lead. The loss can be averted only with difficulty and not always avoided, unless the sponge is filtered. Those who are at times compelled to filter their sponges know what a mess it makes; they resort to it only in emergencies.

I have performed many experiments in an effort to make the sponge tough and adherent so that there would be no difficulty in collecting and pressing it into a ball suitable for cupellation. While performing those experiments, it was observed that excellent sponges were always obtainable with solutions that were pure and only slightly alkaline. An effort was made to counteract the impurities and neutralize the alkalinity by the addition of various salts and acids. The inorganic salts were harmful or useless. Nitric and hydrochloric acids gave low assay results. Sulphuric acid was beneficial when the right amount was added, but even a slight excess gave an insoluble lead sulphate on addition of lead acetate, whereas not enough produced no improvement in the sponge. Later, acetic, oxalic, and other organic acids were tried. With the exception of tartaric acid all were unsatisfactory, although less so than the stronger inorganic acids.

Tartaric acid gave good results in the preliminary trials. Subsequently experiments were made in which the amounts of tartaric acid, zinc dust, lead acetate, and hydrochloric acid were varied and the quantity of each reagent that gave the best results was determined. Other series of experiments determined the method of procedure. The process thus devised was tested by assaying nearly 400 actual mill-solution samples, all in duplicate—the originals by the tartaric-acid method and the duplicates by the other standard methods. Slightly larger buttons were obtained by the tartaric-acid method. The evaporation in litharge gave the next-best results, but the time and effort required to evaporate, fuse, and cupel was, of course, much greater. In all these experiments, the solutions to be assayed were heated nearly to boiling, but it was proved later that heating was unnecessary. The action is complete at room temperatures, although a little more chemicals and time are required.

The method of procedure that gave the best results is as

follows: Prepare the lead-acetate solution by dissolving 300 gm. of the salt in 1000 cc. of water. Always heat this solution to boiling before using it in order that a sponge of uniform size may be obtained. Take 5 to 10 assay-tons of the sample and add $\frac{1}{2}$ gm. zinc-dust. Stir and add $\frac{1}{4}$ to $\frac{1}{2}$ gm. of solid tartaric acid, or the equivalent amount dissolved in water. As soon as the acid is dissolved, add 10 cc. of the prepared lead-acetate solution and $2\frac{1}{2}$ gm. of zinc-dust. Stir vigorously and add 10 cc. of hydrochloric acid and stir again. The sponge will form rapidly, and the solution being assayed will become perfectly clear in about 10 minutes if cold and one to three minutes if it is heated. Finally add sufficient hydrochloric acid to dissolve the excess zinc. When solutions are not heated, use $\frac{1}{2}$ to 1 gm. tartaric acid and 3 gm. of zinc-dust, instead of $2\frac{1}{2}$ gm. Otherwise the procedure is the same. The lead sponge formed in this manner will be tough and adherent. Any loose particles will readily cling to the bulk when the solution is poured off. The sponge can be washed once or twice by decantation and then dropped into the hollow of the palm and pressed into a ball ready for cupellation. It should be wrapped in a small piece of lead foil, for there is a danger of crumbling it when it is being placed in the cupel with a pair of hot tongs.

The tartaric acid, zinc-dust, lead acetate, and hydrochloric acid must be added in the order given, but the time interval is not important. They can be added one immediately after another or at any time the assayer wishes to do so. The sponge forms so rapidly on addition of acid that a considerable amount of zinc is trapped in it. Part of the sponge projects above the solution and the zinc confined there is inaccessible to the action of the acid. For that reason the hydrochloric acid added to dissolve the excess zinc should be dropped directly onto the sponge.

IRON AND STEEL can be successfully made from the 'black' sand of the Pacific coast, according to an article by James L. Avis, Jr., in the 'Western Machinery World'. Virtually all these iron-bearing sands are magnetic and carry a high proportion of titanium, ranging from 8 to 11%. This titanium content tends to cause a clogging of the bosh of the furnaces and has been the cause of the abandonment of most attempts at reducing these sands, for the simple reason that no means for its elimination had been discovered. Obviously the sand must be briquetted and the nature of the binder must be such as to resist disintegration up to the melting point; and the absorption by the slag of the titanium must be accomplished. The New Era Iron & Steel Co. has erected an experimental plant at Sedro Woolley, Washington, where pig-iron is produced at a cost of \$24 per ton. The electric smelting of briquettes from these sands is accomplished, converting them into any grade of steel, and particularly the special alloy-steels. As long ago as 1905, experiments were being carried on in different parts of the world, and tool-steel was successfully produced from titaniferous, sulphurous, and other iron ores by electric smelting.

Ancient South American Smelting Practice

*It is common practice in South America to roast the copper ores in reverberatory furnaces. Including the fire-place at one end and the flue at the other, the furnace is about 16 ft. long and 4 ft. broad; the fire-place and roasting-hearth are on the same level, raised 3 ft. above the ground; the fire-place is about 3 ft. long by 4 ft. wide. Three mud arches, with flat tops thrown across, serve instead of fire-bars, the ashes falling down into the pit below and between the chinks in the arches; the fire-place is separated from the furnace by a partition, through which, by means of a low arched communication, the flame is thrown directly on the ore. The heated air and the fume find exit through another arched opening at the opposite end into a chamber, above which there is a columnar chimney about 4 ft. high and of 8-in. internal diameter; through this flue the heated air makes its escape. In the front of the fire-place is an arch opening for the introduction of fuel, which, being resinous (bushes of jarillo), causes a great blaze; it quickly burns to ashes without leaving any permanent cinders. No door is therefore necessary, as the fire requires constant feeding. On the other side of the furnace is an opening onto the hearth, by which the ore is introduced; this opening is closed with a few rough bricks and is plastered with mud.

GRINDING THE ORE. This is accomplished by the same means whether it be previously roasted or not. A rude *trapiche* or mill is constructed. It differs from those used in Chile, already described,† and is built more on the principle of the Spanish flour-mill, except that instead of an upper stone revolving horizontally upon a lower one of equal size, there are two rough and heavy fragments of rock, affixed by hide ropes from each end of a horizontal arm; these are dragged around upon the lower stone. The process therefore is one of grinding rather than of crushing; the moving power is water. Here, as in all the mills of Spanish construction, a small current from a height of about 8 ft. runs in an inclined trough and falls into a series of wooden cups, hollowed out of so many spokes radiating horizontally from a vertical shaft, fixed in a central pivot. The impetus given by this small quantity of water is considerable, and is communicated to the vertical shaft, whose upper end passes through a hole in a horizontal and circular mill-stone, 5 ft. in diameter, and extending a few feet above it. Across the upper part of this shaft a piece of wood is fixed horizontally, forming two opposite spokes, from whose ends the two blocks before mentioned are loosely hung. As the vertical shaft makes about 60 revolutions per minute, the two blocks are

therefore dragged around as many times in the same period. A man attends to the feeding of the mill with ore and to the removal, by means of a wooden scoop, of the powder when it is sufficiently ground. The next process is the sifting of the powder through a cylinder, covered with coarse cloth, and having a door in the side to introduce the pulverized ore. The cylinder is enclosed in a wooden case, and is turned by a winch-handle; the finer powder passes through the canvas, and falls to the bottom of the case; the coarser particles are taken out at the door, and are carried back to the mill to be re-ground.

The smelting and refining of copper is conducted by a process certainly neither the most economical nor scientific, as regards the quantity of metal produced; though

FURNACE USED FOR SMELTING COPPER ORE

perhaps the small expense incurred more than counterbalances the loss of copper in such rude metallurgic operations. It does not often happen that reduction can be performed in the immediate vicinity of the mines; more generally the plant is at some distance, where wood and water can be obtained in sufficient abundance; in such a case the ore is brought from the mines on the backs of mules. The first process of reduction is that of roasting, which is conducted in a rude furnace excavated from the foot of the hill. One of the perpendicular walls, part of the side-walls, and the hearth, are formed of the hill itself; the front wall and part of the sides are built of sun-dried bricks, or of stones cemented by mud. Part of the furnace is prepared with a mixture of cement and calcined bones, in order that it may resist the fire; it would otherwise be contracted by the heat, and crack; and through these cracks the metal would escape. The ore and the fuel can thus be thrown easily from the hill into the top of the furnace, which is always left open. A quantity of wood is first added, then a portion of ore, then alternately wood and ore, until the furnace is charged. The ore is carried, in wooden troughs called bateas, to the furnace by peones, the bateas being apportioned to a number of mule-loads of wood, as circumstances may determine. The fuel used is mimosa, or any

*Abstracted from 'Travels in Chile and La Plata', by John Miers, published in 1826.

†See 'M. & S. P.' of October 1.

thorny wood that can be procured. The fire is lighted at the bottom, a blast of air is constantly maintained by bellows, which are circular, single valved, in pairs, and in some cases are worked by a water-wheel, from two crank motions; but more often they are worked by hand.

The two bellows are fixed vertically, side by side, upon a wooden base. A tube, generally formed of the osseous stem of the torch thistle or *Cactus peruviana* and covered with mud, proceeds from a central hole in each front fixed board; and these tubes, converging, are inserted into a small hole made for the purpose in the bottom of the furnace. The hind, or movable, bellows-boards being jointed at the bottom to the front boards, a peon stands holding the handle of each in his hands, and, by a violent alternating motion, pushes forward first the one and then the other board, by which action he maintains the continuity of the blast. The fire is kept brisk for about 25 hours; and when the process is considered finished, a tap-hole is opened and there flows out a strange mixture, for the mud lining of the furnace, as well as the adobes, being extremely fusible, are partly melted by the heat, adding to the bulk and to the fluidity of the mass. The fluid mixture flows into a small pit, where it cools, the metallic particles being found in flakes and globules that are interspersed throughout the mass, which is subsequently broken up by a man called a *chanquero*, who, seated on the ground, performs this tedious operation with a hand-hammer.

The slag is first broken into large masses, to separate the flakes and larger lumps of copper, which are placed apart. These are then broken into smaller pieces, which are carefully turned over by the *chanquero*. He, poising them in the hand, can, by practice, ascertain whether to cast them aside for mere slag, whether to break them still further, so as to separate more globules, or to throw them, as they are, among the metallic portions for refining. The hearth of the refining furnace is constructed of solid adobes of sun-dried clay, and is about 15 ft. long, 5 ft. wide, and 3 ft. above the ground. The sides are raised about 2 ft. higher, and the top is arched. There are two chimneys, raised 4 ft. above the hearth, and placed at the corners that are the farthest removed from the fire-place. At each end of the furnace there is an opening; one of these leads into the open air, the other into the fire-place, which is a small chamber built against the end, and is as high as the furnace. Its length is about 8 ft., its breadth about 4 ft., and it is the continuation lengthwise of the whole structure. On the opposite side of this chamber is a large arched opening for the admission of fuel, and on the intermediate side, in line with the two openings of the furnace, is a small aperture, which permits a view of the operations within the furnace at that end.

It is necessary to remove the arched ceiling of the furnace every time the bed is charged. The lumps of metal that collect are thrown in, the ceiling is again closed, and luted with mud. The fire is then lighted, and the furnace is kept at a gentle heat for a day or two, so that it is gradually dried. Finally the fire is raised briskly by throwing into the two large openings of the

chamber, faggots or brushwood, or more generally billets of the torch thistle; it is thus maintained for 48 hours in a glowing state. All the doors or vents are kept open during the operation, to watch progress, and to allow a free exit for the flame at all parts, according to the notion of the natives, who believe that they could not produce the requisite heat if any of the openings were closed. It often happens, as might be expected, that cracks occur in the ceiling or dome of the furnace, through which the heated air escapes. On such occasions nothing more is necessary than to patch it with plastic mud, which is always at hand for the purpose. During the process of reduction, the peones stir the fluid mass; and when the reaction is considered complete, a tap-hole is opened on one side of the furnace, where, the bed being low, the metal has collected. The ground around the furnace into which the metal is to be received is prepared by digging out a number of square holes, about 16 in. long, 12 in. wide, and 4 in. deep, which, when smooth, are covered with a coating of wood ashes, to prevent adhesion of the metal to the earth. A number of small channels communicate from one to another; and as the metal runs from the tap-hole, the molds are filled in succession. The thickness of the cakes that are formed varies from $2\frac{1}{2}$ to 4 inches.

THE currencies of Europe are nearing a stage at which it will be impossible to use them as media of exchange. There is no well-defined line at the crossing of which a currency becomes worthless, but evidently it cannot continue to depreciate without reaching, in time, the point where the public will refuse to give anything for it. It is amazing how long a people will makeshift with money that is on the verge of becoming worthless, simply from the force of custom and because they have no substitute, according to the National City Bank. In Russia, the old unit, the ruble, formerly worth about 51c., now has a value so small that the old denominations have long since passed entirely out of use. Even a thousand-ruble note of the new issues will not buy anything. As the depreciation has progressed the denominations have risen, 10,000, 50,000, and 100,000-ruble notes becoming the common change in use. The Polish mark, nominally worth 23.8c. in money of the United States, is quoted at 0.03c.; the Austrian crown, formerly 20c., is only slightly higher; the crown of Jugo-Slavia, which corresponds to the Austrian unit, is worth a little more, about 0.36 of a cent; the crown of Hungary is worth about 0.1 of a cent. These currencies are near extinction, and live on only because there is nothing to take their places. It is difficult to see how business can be carried on with them, and particularly how any agreement for future performance can be entered into in terms of them. Even small fluctuations in the value of these infinitesimal units would have great effect in the value of commodities. How can any credit be given in terms of money? All past indebtedness is practically wiped out, and while that for the moment may benefit debtors as much as it injures creditors, how dare anyone take a creditors position for the future?

REVIEW OF MINING

H. W. MORSE WILL ADDRESS SAN FRANCISCO SECTION OF THE INSTITUTE

The December meeting of the local section of the A. I. M. & M. E. will be held at the Engineers' Club on Tuesday evening, December 20. H. W. Morse will read a paper entitled 'Present Status of the Treatment of Mixed Copper Ores'. The meeting will be preceded by the usual dinner at 6 p.m.

COPPER AND BRASS RESEARCH ASSOCIATION MEETS IN NEW YORK

The first annual meeting of the Copper and Brass Research Association was held on December 6, at the offices of the Association at 25 Broadway, New York. The following directors were elected to serve for the ensuing year:

R. L. Agassiz, Calumet & Hecla Mining Co.; J. W. Allen, Greene-Cananea and Inspiration; H. F. Bassett, Taunton-New Bedford Copper Co.; H. C. Bellinger, Chile Exploration Co.; Edward H. Blinns, C. G. Hussey & Co.; Stephen Birch, Kennecott and Braden Copper companies; F. H. Brownell, American Smelting & Refining Co.; J. Parke Channing, Miami Copper Co.; F. S. Chase, the Chase companies; Carl F. Dietz, Bridgeport Brass Co.; Walter Douglas, Phelps Dodge Corporation; B. Goldsmith, National Brass & Copper Co.; E. O. Goss, Scoville Mfg. Co.; Robert H. Gross, East Butte Copper Mining Co.; Charles Hayden, Chino Copper Co.; U. T. Hungerford, U. T. Hungerford Brass & Copper Co.; C. V. Jenkins, Chino Copper Co.; C. F. Kelley, Anaconda Copper Mining Co.; H. B. Paull, Calumet & Arizona Mining Co.; R. M. Raymond, United Verde Extension Mining Co.; H. J. Rowland, Rome Brass & Copper Co.; A. B. Seelig, Michigan Copper & Brass Co.; W. Parsons Todd, Copper Range company.

The directors elected the following officers for the year 1922: president, R. L. Agassiz; vice-presidents, C. F. Kelley and F. S. Chase; treasurer, Stephen Birch; secretary, W. S. Eckert; manager, William A. Willis.

RICH ORE DISCOVERED NEAR IDAHO SPRINGS, COLORADO

A dispatch from Idaho Springs says that the richest gold discovery in Clear Creek county, Colorado, for years has been made on unpatented property, the Queen Elizabeth claim of the Frank J. Hayes Mining Co., in Virginia canyon. This company has been driving an adit, now in 225 ft. Recently a winze was started about 175 ft. from the portal. The first round of holes disclosed 10 in. of ore that assayed 8.50 oz. gold and 17.60 oz. silver. With the winze at 10 ft. the streak has widened to 18 in. and a sample taken over its entire width gave 68.90 oz. gold and 11.85 oz. silver per ton. The ore is now being sacked. The property lies on the opposite side of the canyon to the Treasure Vault mine with a record for past production of high-grade ores. James R. Noland is vice-president of the company.

IRON CAP V. ARIZONA COMMERCIAL—SUIT STARTS AT GLOBE

In the Superior Court of Gila county, Arizona, the hearing

of the apex suit of the Iron Cap Copper Co. against the Arizona Commercial Mining Co. to decide the questions of extra-lateral rights to sundry orebodies, started on December 12. Presiding will be Judge Samuel Battee of Tucson. Judge G. W. Shute of the Gila County Court having expressed a sense of disqualification. Horace V. Winchell, who has appeared as an expert witness in several important apex cases, will appear for the plaintiff, as well as R. H. Hunt and W. H. Wiley of Los Angeles. For the Arizona Commercial, expert testimony will be given by Albert Burch and G. M. Hjorge, the latter for several years geologist for the Old Dominion and Arizona Commercial companies. Edward T. McClennan of Boston is chief counsel for the Arizona Commercial, and Morris & Mallot appear for the Iron Cap.

TONOPAH WILL PRODUCE \$650,000 IN DECEMBER

At the present rate of production the value of silver bullion shipped from Tonopah during the month of December will run over \$650,000. Reports of clean-ups for the last half of November shipped the first week of December indicated a steady increase in the tonnage and value of ore. The MacNamara, the smallest mill, chiefly concerned with treating custom ore, announced that beginning this month the company will resume shipments of bullion every 10 days instead of waiting for the usual 15-day period. This indicates an increase of 30% in the output of bullion. The Tonopah Belmont company shipped 68 bars weighing 129,877 oz., valued at \$149,000; the West End sent out 25 bars weighing 49,800 oz., valued at \$55,000; Tonopah Extension shipped 24 bars weighing 43,000 oz., valued approximately at \$48,500; the MacNamara shipped 7 bars worth \$14,000; and the Tonopah Mining Co. shipped 23 bars for which the company furnished no estimate of weight or values.

UTAH COPPER DECLARES DIVIDEND OF 50c. PER SHARE

At a meeting of the directors of the Utah Copper Co. in New York City on December 7, a dividend of 50c. per share was declared, payable December 31. During the present year, Utah Copper has paid its stockholders \$2.50 per share in dividends, or a total of \$4,061,225. The grand total of dividend disbursements to the close of 1921 will be \$115,570,887. The company recently put a steam-shovel to work at Bingham, for the purpose of loading several thousand tons of ore. When operations were suspended last April the company was making metallurgical tests at the Arthur plant on a practical scale, and it has been decided to complete these experiments during the present winter.

NEW STACK AT U. S. SMELTER AT MIDVALE, UTAH, COMPLETED

The new smoke-stack at the Midvale plant of the United States Smelting Co. has been completed in record time, less than four months being required for its construction. Flue-connections from the furnaces to the stack have also been completed, and gases are now being discharged at a point 178 ft. higher than was possible with the old steel stack. All of the material for the stack was procured within a

radius of ten miles of Salt Lake City. The steel was furnished by the Utah Steel Corporation; the radial brick and Weiderholdt tile were made by the Utah Fire Clay Co. The foundation of the stack is of reinforced concrete, octagonal in shape; it is 87 ft. in diam. and 10 ft. thick. The lower 5 ft. is a solid block, and the upper 5 ft. is stepped, making the top 51 ft. across. The stack is 451 ft. 4 in. high. The outside diameter at the base is 46 ft. 1 in.; the inside, 39 ft. 5 in. At the top, the outside diameter is 29 ft. and the inside 24 ft. The coping on the top is 30 in. wide. For the first 125 ft. the outer shell is made of radial brick, filled with reinforced concrete. There is a 3-in. air-space left, and then a lining of 4½-in. soft glazed brick, hard-fired, and built for insulation. Eight lightning rods, tipped with platinum, have been installed. The rods are connected with ½-in. copper cables that are carried to a depth of 14 inches in the ground. Provision has been made for taking samples of smoke from various points in the stack. There was used in the construction of the stack 15 cars of cement, and in the foundation, 12 cars, or a total of 981 tons. Thirty-three cars of sand was used in the stack construction and 21 in the foundation, or 2349 tons. Forty cars of gravel, or 2295 tons, was used in the foundation. Two carloads of Utah Copper tailing was used in the brick-mortar lining, making it acid-proof. Sixty-five cars of brick and tile was used, or 2174 tons. The material used in the entire structure totaled 189 carloads, or 8451 tons. Since the beginning of the work, the ground has settled but 1½ in., but this is evenly distributed. The Weiderholdt Co. of St. Louis had the contract for the work. A crew of 31 men was employed, under J. D. Martin, superintendent. It is stated that the cost was about \$150,000.

VALUATION ENGINEERS TO BE APPOINTED BY TREASURY DEPARTMENT

The Internal Revenue Bureau contemplates the appointment of 75 valuation engineers, of whom 45 will be detailed to the natural resources subdivision, 30 on valuation of oil and gas, and 10 on coal, timber, and metals. Answering complaints that the tax law and forms are complex, Internal Revenue Commissioner Blair says they will continue so as long as business is complex.

ENCOURAGING OUTLOOK FOR ZINC MINES IN WISCONSIN

Offerings on zinc ore increased substantially in the Wisconsin zinc district during November, the base price for 60% blende going to \$29 per ton; sales were made which brought the price on premium grade to a point close to \$31. Compared with the quotations obtaining in the Mo-Kans-Okla districts Wisconsin prices were far ahead, the difference in price arising from the advantage enjoyed by Wisconsin producers in nearness to the zinc smelters of the Illinois coal-field and the lower freight-rates. Developments during the month are significant. The Illinois Zinc Co., down for the better part of the current calendar year, has heated up its big works ready for operation. This means that this concern will be in the field for high-grade blende. The Mathieson & Hegeler Zinc Co. of LaSalle, Illinois, bought the entire manufacturing plant of the Smeeton Shingle Co. and its rights, and began the manufacture of Smeeton zinc shingles, in three sizes. This will mean an increased market for zinc ore.

Lead ore experienced a decline in price but not sufficient to deter prospect work and selective mining. The base price dropped from \$55 to \$52.50 per ton, base 80% metallic content. Production was increased and shipments were made. Heavy rains over the latter part of the month retarded operations at mines, especially in districts somewhat removed from the railways, and dependent on dirt roads for

haulage. Several mining companies gave attention to road construction and ballasting with tilling. Outlying producers find road building to be a good investment.

FREIGHT-RATE HEARINGS

From December 14 to 21 the Interstate Commerce Commission will hear the railroads in its investigation of the rate situation; it announces a schedule for hearings arranged according to commodities after cross-examination of the railroads beginning January 9. The Commission will seek to determine whether present rates are reasonable in the aggregate in the country as a whole or in the rate groups, and whether rates on specified commodities or descriptions of traffic are reasonable. It will also determine the rate of return to which railroads may be entitled after March 1 when the present 5½% guarantee expires. Special consideration will be given to coal transportation. In its investigation of the railroad situation the Senate Interstate Commerce Committee heard Frank J. Warne on behalf of railroad workers who criticized financial holdings of railroad officials in companies from whom purchases of coal, steel, oil, and other supplies are made, alleging that it resulted in high prices and high freight-rates.

ONE-THIRD OF OUR COPPER EXPORTS GO TO GERMANY

More than one-third of the copper exported from the United States in the first ten months of this year was consigned to Germany, as 185,000,000 lb. of the 494,000,000 lb. shipped abroad, went to that country. By including the clearances to Holland, intended largely for German consumption, shipments to Middle European countries went above 200,000,000 lb. The combined takings of France and Great Britain did not equal the shipments to Germany. Although it has figured in copper market gossip as a heavy buyer of the metal, Japan's takings, as measured by exports to that country, were not much more than half last year's total, the exports up to November 1 amounting to 42,000,000 lb., against 82,000,000 lb. in the first ten months of 1920. Copper sales in the month just closed were the largest of any month this year. Between 160,000,000 and 170,000,000 lb. of metal was contracted for by both foreign and domestic buyers. A large proportion of this is for domestic delivery.

Several of the largest producers of copper, having sold all they care to at current prices, have withdrawn from the market and are holding their metal for 15c. per pound. This is true of the United Metals Selling Co., which has remained aloof from the market for some time, waiting for higher prices.

INTERPRETATION OF THE RECENT WAR MINERALS RELIEF ACT

Promulgation of official interpretation of the broadened provisions of the War Minerals Relief Act will soon be made by Secretary of the Interior Fall. It is estimated that 670 cases are affected. Tentative plans under which the Commission expects to take up re-opened cases calls for the distribution of a revised questionnaire which claimants will be asked to submit along with additional evidence to support claims for further consideration. It is expected that practically all the 610 cases which the Commission has previously rejected under the request or demand decision will be reconsidered. There will probably be 50 cases to be considered which involve the question of time of submitting the claim, the new law reversing the decision made by the Comptroller of the Treasury by recognizing claims which actually started on their way to the Commission within three months after the passage of the original bill, without requiring that they be in the hands of the Commission within that time. At

least three additional claims will come up for reconsideration on the grounds that errors were made in awards which have already been granted, and it is likely that several other cases involving the question of commercial value and the charging of loss directly to government stimulation will come up. The vast majority of cases which have been rendered eligible for additional consideration by the new law have never been subjects of initial investigation of auditors or field-engineers. Field-work will hardly be possible on a large scale until spring. The time which has elapsed since these claims were last brought before the Commission is also expected to place a handicap upon field investigations.

COAL MINING INSTITUTE MEETS AT PITTSBURGH

The 35th annual meeting of the Coal Mining Institute of

ARIZONA

Clifton.—The new organization of the Clifton-Morenci Branch of the Phelps Dodge Corporation has been announced by Walter Douglas, president. The manager is J. P. Hodgson, former superintendent of the Copper Queen mines at Bisbee and later in charge of the Detroit mines and works, operated as the Phelps Dodge Morenci Branch. For assistant he will have William Savin, who comes from the Copper Queen at Bisbee. Norman Carmichael will become consulting engineer for the Phelps Dodge Corporation, with offices at New York. He has been with the Arizona Copper Co. since 1905, and for years has been manager of this British company, which lately transferred its Arizona interests. Announcement is made that no large plans of rehabilitation or change will be put into execution now, but work

Interior of Inspiration Mill at Miami, Arizona

America was held at Pittsburgh, Pennsylvania, on December 7, 8, and 9. Papers read included the following: 'The Mineral Resources of Pennsylvania', by George H. Ashley, State Geologist; 'Safety Gates and Safety Appliances for Cages and Hoisting Shafts', by William G. Duncan, Director of Mining Extension Work, State College, Pennsylvania; 'Explosion-Proof Mine Locomotives', by L. C. Illsley, electrical engineer, U. S. Bureau of Mines; and 'Comparative Haulage Costs—Animal and Mechanical', by A. F. Strouse. There were ten discussions at the Question Box Sessions on various phases of coal mining. At the annual dinner there was a large attendance. H. Foster Bain and George Otis Smith, directors, respectively, of the U. S. Bureau of Mines and Geological Survey, were speakers. Inspection trips included a visit to the 5000-ft. Liberty vehicular tunnel being driven on the south side of Pittsburgh, also to the Bureau of Mines Experiment Station and the mining department of the Carnegie Institution of Technology. H. D. Mason, of the Mine Safety Appliance Co., Pittsburgh, Pennsylvania, is secretary of the C. M. I. A.

on remodeling of the Arizona Copper concentrator No. 6 will be started at once on plans already made.

Globe.—The Superior & Boston company, after six months of inactivity, has resumed mining and will send copper ore to the Miami plant of the International Smelting Co. This announcement has been made by E. G. Deane, superintendent. An agreement has been made with the smelting company to treat copper ores carrying silver. Much ore already is available in the mine-bins, averaging about 8% copper and 30 oz. silver. It has been held because no copper smelting was being done at El Paso. Three cars of silver ore sent to El Paso netted the company about \$18,000. The silver ore has persisted to an unlooked-for depth, and silver and copper alike are found on the 400- and 600-ft. levels of the Footwall vein. A cross-cut has been started on the 200-ft. level to connect the McGraw shaft with that on the Eclipse claim, a distance of 900 ft., in virgin ground.

Jerome.—Directors of the Dundee-Arizona Copper Co. have just visited the property and it is reported that it is the

intention of the company to start operations the first of the year. The mine is at present flooded. Some promising veins were opened prior to pulling the pumps; and it is upon these that it is proposed to sink a 500-ft. winze. The company recently secured a permit from the Corporation Commission to sell 61,120 shares of stock.

Kingman.—The Tom Reed Gold Mining Co. has announced its intention to accept custom gold ores and operate its mill as a custom plant. A test-run is now being made at the mill to get data on the cost of treating ore of variable grade. There is a considerable tonnage of payable gold ore developed in the smaller mines in the Oatman district which can now be mined. The operation of the Tom Reed mill as a custom plant will no doubt be an incentive to more active prospecting.

Development on the 100-ft. level of the Gold Chain mine has opened high-grade silver ore 140 ft. east of the shaft. The ore, which is oxidized, was opened after passing a fault. A cross-cut is being run. Development to date has opened 40 to 50 ft. of fair gold ore on the 100-ft. level which is 200 ft. below the outcrop.

Messrs. Good and Hodge, who have a lease and bond on the Enigma claim in the Weaver district, have opened ore running 1800 oz. in silver and \$200 in gold per ton at the bottom of an old 40-ft. shaft. The shaft has been sunk several feet into the ore and shows the vein carrying the high-grade to be eight inches wide. The Enigma once produced some bonanza ore.

The 70-ton mill of the Kaaba Mining Co., 30 miles east of Kingman, is being made ready for operations. The Kaaba mine is said to have 30,000 tons of vanadium ore blocked out; it averages $1\frac{1}{2}\%$ vanadium oxide.

Machinery at the White Hills Mining Co.'s mines is being installed rapidly. The many lessees on the property are opening a greater tonnage of ore than was anticipated. At present the company is carrying on sinking at the G. A. R. and Occident mines. A new orebody of rich silver ore has been opened on the 200-ft. level of the G. A. R. mine. The ore-streak is said to be five inches wide and has been drifted upon for 30 ft. There are at present 30 men working at the property.

Phoenix.—No defence has been offered by the Arizona Hercules Copper Co. to a foreclosure suit brought against it here by the Empire Trust Co. of New York, trustee, and default judgment will be entered soon by the plaintiff's attorney, Richard E. Sloan. The principal sum is \$3,000,000, with \$577,000 added interest unpaid; 90% of the defendant corporation's stock has been held by the Ray Hercules Copper Co., which has been operating mines on Mineral creek, Pinal county, east of the main workings of the Ray Consolidated, its claims covering about 200 acres. The debt was incurred through construction of a modern flotation-mill, with Diesel power-plant, an efficient hoist, concrete ore-bins, shops, railroad connections, a bridge across Mineral creek, and other improvements through which there was to be handled at least 600 tons of ore per day. The mill ran only a few weeks. There is said to be developed an orebody estimated at 25,000,000 tons above the 500-ft. level, with 10,000,000 tons claimed to exceed 2% copper. There had been dissension within the company and some litigation with the Ray Consolidated. For more than a year the mine and works have been inactive. The stock has fallen from about \$5 per share to a late quotation of 25 cents.

CALIFORNIA

Grass Valley.—H. J. Snyder and associates, of San Francisco, are re-opening the Good Hope mine situated in the Spenceville district. A 100-ft. shaft, sunk many years ago, revealed a well-defined vein.

Jackson.—It is reported that excellent ore has been found in the course of development at the old Moore mine.

Susanville.—A cyanide plant is to be erected at the Osterbloom mine situated in the Milford district. A. J. Osterbloom, the owner, reports that a large body of medium-grade ore has been opened.

Westpoint.—The Westpoint Gold Mines Co., controlled by the North Star Mines Co. of Grass Valley, has taken an option to purchase the Combination group of claims. According to A. B. Foote, superintendent for the North Star company, the erection of a 60-stamp mill is being considered. The group includes the Lone Star mine and the Keltz mine, as well as a number of smaller properties. A number of shafts and extensive drifts have exposed ore in the different mines, although the record of production in past operations is not stated.

COLORADO

Boulder.—The Potosi-Caribou Mining Co. has completed arrangements to operate the Boulder County milling plant, providing transportation for ores can be secured. Motor-trucks will probably haul the ore by contract. The Potosi mine has a large tonnage of mill-ore available. The company is financed by New York and New Jersey capital.

Breckenridge.—The leasing company headed by George Robinson and W. T. Keough of Summit county, operating the Warrior's Mark, has opened high-grade ore assaying as high as \$1000 per ton at a depth of 100 ft. from the surface. The pay-streak is 10 in. wide and native silver is found in the vein. A consignment is being prepared for shipment to the Arkansas Valley smelter at Leadville before the first of the year. The Warrior's Mark is situated about one mile from the Belmont switch near Boreas Pass, and the road will be kept open during the winter.

Central City.—Returns from a shipment from the Frontenac to the A. V. smelter at Leadville showed 1.82 oz. gold and 12.5 oz. silver; net return, \$641.62 for a 20-ton lot.

Colorado Springs.—Directors of the Cresson Consolidated Gold Mining & Milling Co. on Tuesday, December 6, declared a quarterly dividend of 5c. and an extra dividend of a like amount, making the distribution \$122,000 or at the rate of 10c. per share on stock issued. The dividend is payable January 10, 1922, to stock of record as of December 31, 1921. With this payment stockholders will have received \$8,979,102 in dividends. The property of the company, the Cresson mine on Raven hill at Cripple Creek, continues to produce heavily.

Cripple Creek.—Production of the gold mines of the district for November, while showing decrease of 1740 tons as compared with the October figures, had an increased value of \$9218 due to a better grade of ore treated at the Golden Cycle mill. The figures reported by the mills are: Golden Cycle, 21,000 tons, \$15.50 average, value \$315,000; Portland company's Independence mill, 23,200 tons, \$4.30, value \$99,700; Lincoln M. & R. Co.'s Ironclad mill, 400 tons, \$1.50, value \$600.

The Golden Cycle M. & R. Co. paid its stockholders a 2c. dividend amounting to \$30,000 on December 10, bringing the total dividends to date to \$9,633,500. As shown by the monthly report the Cycle mill is treating all ores shipped from the district, and in November received 540 cars broad-gauge.

Work has been resumed on the Hoosier mine, at Hoosier Pass, between Tenderfoot and Globe Hills, by the Grafton Gold Mining Co., the original owning corporation, incorporated in 1896. Diamond-drill contractors have been engaged and are now drilling in search of new ore-shoots.

Ouray.—The Chipeta M. M. & S. Co. has completed the installation of machinery and is now using air-drills in development. Work is to be continued during the winter in the H. A. C. mine, where surface showings are encouraging. —The Revenue is preparing to resume and the Terrible vein will be more fully developed. A new company organ-

ized by Bradlish P. Morse will operate the property.—A compressor has been installed on the Barstow mine and lessees are operating.

Telluride.—The Smuggler Union mill shipped 60 cars of concentrate to the smelter and the Tomboy mill 45 cars during the month of November.

IDAHO

Kellogg.—The Bunker Hill smelter is now operating two furnaces and is treating about 600 tons of ore per day. The second furnace was blown-in the latter part of November. It was made necessary by the large accumulation of ore at the smelter. Through concessions in freight-rates the Kellogg plant is now in position to secure shipments from western Montana, northern Idaho, eastern Washington, and British Columbia, sections which in the aggregate produce considerable tonnage and which have a promising future in respect to steady increase in mineral production. The Bunker Hill plant has four furnaces and is therefore in position to meet all requirements of the field it serves.

Leadore.—The E. H. and W. C. Dewey Investment Co., of Nampa, has taken a bond and lease on the Kimmel mine and adjacent claims. The company will start active development at once.

Mountain Home.—The Federal Power Commission has granted a preliminary permit to the Elmore Copper Co. The company proposes to build a dam on the south fork of the Boise river 25 miles above Arrowrock dam, where it is expected 3000 hp. can be developed which will be used at the company's mine and for general purposes. The company will examine foundations for the dam and is given two years to study the available flow of water in Boise river.

MICHIGAN

Houghton.—Predictions that November, the last full month of the season of navigation, would be the banner month for copper shipments out of the Lake district, are borne out by the official records. The total, 22,532,000 lb., is more than double the amount shipped out in October when 10,840,000 lb. went forward and compares with 7,028,000 lb. for September. It also surpasses the total for November 1920 of 16,690,000 lb. Calumet & Hecla's shipments by boat from its smelter docks at Hubbell totaled 9,070,000 lb., while 904,000 lb. was shipped from the Dollar Bay docks, where Osceola and Isle Royale copper is stored. From the Michigan smelter, which treats Copper Range, Mohawk, and Wolverine mineral, 8,828,000 lb. was shipped. Quincy sent out 3,730,000 pounds.

So far as this district is concerned the metal situation gives rise to optimism, for it means that the mines now closed must give attention soon after the first of the year to plans for resumption. While operations may not actually start until spring, considerable work will have to be done in the way of preparation.

Calumet & Hecla is confronted with problems of deep mining but it is solving them satisfactorily. Never in the history of the company has the routine of Calumet & Hecla's operations been better organized than at present and in a reorganization of working forces, such as will be necessary when operations are resumed, considerable economy will be effected. The abnormal labor costs of the war years of course will be dispensed with and in addition each department will be conducted in strict accordance with its actual necessities. In the matter of power alone, a big saving will result from the extension of the company's power lines from its plant at Lake Linden to the subsidiary mines north of Calumet. These mines, with the exception of Ahmeek, purchased power heretofore from a private company. In so far as possible steam equipment will give way to power-driven machinery, including electric pumps and underground electric haulage. In Calumet & Hecla proper, once operations

are resumed, the haulage drift at the 81st level of the conglomerate shafts will be pushed through to completion as rapidly as possible, making possible eventually a reduction of costs in the mining of conglomerate ore at depth.

MONTANA

Elkhorn.—The East Butte Copper Mining Co. is operating its 150-ton cyanide plant. The vein is said to be 30 ft. wide; the ore averages about \$8 per ton in gold.

Helena.—The Carbon Hill mine, in the Grass Valley district, has a carload of ore that will run \$50 per ton in silver. Silver-bearing ore is being shipped from the Franklin mine dump to the East Helena smelter.

NEVADA

Elko.—The Catlin Shale-Oil Products Co. has purchased the experimental plant formerly operated by the Southern

Pacific Co. The equipment will be added to the enlarged plant being constructed by the Catlin company, which is engaged in producing gasoline, distillate, lubricants, and paraffine wax from shale. Development of the shale deposits near Elko is being hastened; a large tonnage of shale is reported to be exposed.

Pioche.—Ore shipments for the week ended December 9 were as follows: Black Metals Mining Co., 215 tons; Bristol Silver Mines, 320; Pioche Assay Office, Mascot lease, lot No. 1, 40. Leasing operations are increasing in the district. At the present time there are more active operating properties than for a number of years past. These operations, though small, should do much toward the future development of the entire district.

Tonopah.—The Tonopah Extension Mining Co., which recently acquired the Cash Boy mine as a result of a compro-

mise of an apex dispute, is preparing to develop the property at greater depth. Connection will be made from the lower workings of the Extension mine.

The shaft of the Tonopah Divide mine has reached the 1200-ft. point and the work of cutting a station is well under way. While it is being prepared a cross-cut will be driven south-west, toward the main vein, for a sufficient length to provide space for handling timbers and storing tools and supplies while further sinking is in progress. The company has purchased from the Jumbo Extension Mining Co. the 100-hp. electric double-drum hoisting-engine formerly in use at the Velvet shaft of the latter company. One of the raises from the eighth level, near the south-east boundary of the property, will connect with the drift on the fifth level at a point where that level was connected with the Gold Zone workings. This will provide good ventilation throughout all workings to the eighth level. Shipments of ore to the Belmont mill at Tonopah continue at the rate of 50 tons daily.

The county commissioners of Nye county are taking steps to place the roads communicating with the principal outlying camps in first-class shape. The first project was an entirely new road to Royston to take it out of Esmeralda county. The route takes a high line winding around the hilltops and using part of the old Liberty road. This will shorten the distance between Tonopah and Royston four miles. Orders were given recently for a road gang with two motor-trucks to be placed on the road leading to Groom on the border of Lincoln county. The old route over the Bellehelen summit will be restored and by the building of a cut-off it is claimed that the distance to Eden Creek and Reveille will be shortened 16 miles.

UTAH

Alta.—A new orebody has been opened in the Emma Silver mine, according to M. M. Johnson, consulting engineer. A short time ago, a drift was started south, along the Montezuma fault. Four inches of high-grade silver-lead sulphide was found; and this ore has opened to a width of four feet.—About four feet of snow has fallen so far this winter in Alta.

Bingham.—The Montana-Bingham Mining Co. is now shipping more than 100 tons of ore per day to the Garfield smelter. This ore is low in copper and high in iron, and makes an excellent fluxing material. The company employs 70 men.

Eureka.—The Grand Central Mining Co. will pay a dividend of 1½c. per share on December 20. This is dividend No. 75, and will total \$9000. On January 10 of this year the company paid a dividend of one cent per share.

During the week ending December 3, the output of ore totaled 166 cars, of which 38 cars were shipped to the Tintic Milling Co.'s plant. The Tintic Standard shipped 52 cars; Chief Consolidated, 42; Victoria, 17; Dragon, 14; Eagle & Blue Bell, 10; Iron Blossom, 8; Colorado, 4; Empire Mines, 4; Centennial-Eureka, 3; Swansea, 3; Gemini, 3; Alaska, 2; Bullion-Beck, 1; Gold Chain, 1; Sunbeam, 1. Output the previous week totaled 170 carloads.

Park City.—Directors of the Park-Utah Mining Co. declared an initial dividend of 5c. per share on December 5. This called for the distribution of \$50,000, and payment was made on December 15 to stockholders of record December 10. The Park-Utah is one of the most successful mines developed in Utah in recent years; it is controlled by the Judge interests. The company was incorporated in 1917, but development was not undertaken in earnest until 1919, owing to war conditions. Work was started from a point about 10,000 ft. in from the portal of the old Ontario Drain Tunnel. The main adit in the property is the 1500-ft. level. The company is shipping about 2000 tons of ore per month, all of which comes from development work. It is stated that

the net smelter returns indicate an average value of between \$45 and \$50 per ton. George D. Blood, formerly mine manager of the Silver King Coalition mine, is general manager for the Park-Utah.

Ore shipments for the week ending December 3 totaled 2069 tons, as compared with 2110 tons for the preceding week. The Judge allied companies shipped 967 tons; Silver King Coalition, 709; Ontario, 393.

Richfield.—It is reported that the Mineral Products Co., which is said to be controlled by the Armour interests of Chicago, will install an improved reduction plant within 90 days, to treat the immense alunite deposits owned by the company in Pinte and Sevier counties. The company suspended operations about a year ago, giving as a reason the low price of potash. It is stated that a chemist named Hansen has perfected a process for the reduction of alunite that will permit of a comfortable margin of profit at the present quotations for potash.

Salt Lake City.—A second hearing was held before Judge Tillman D. Johnson on December 11, in the case of the Utah-Apex Mining Co. v. the Utah Consolidated Mining Co., due to failure of the two companies to agree upon the value of the ore taken from the Utah-Apex mine at Bingham by the Utah Consolidated. The first statement filed by the Utah Apex gave the value of the ore unlawfully extracted as being "in excess of \$1,000,000", whereas the Utah Consolidated placed the figure at about \$500,000. Judge Johnson ordered both companies to prepare new estimates. The revised figures filed by the Utah-Apex total \$1,171,679.26, while those submitted by the Utah Consolidated are approximately \$1,070,000, a difference of about \$100,000.

WASHINGTON

Seattle.—The 26th Annual Winter Session of the College of Mines, University of Washington, will be held during the 12 weeks from January 5 to March 22. This session is open to any interested man who can read and write English. The expenses will be limited to a tuition fee of \$15, laboratory deposits to cover materials actually used, and the cost of the necessary text-books. The training consists of lectures with laboratory practice, for which the laboratories of the College of Mines are thoroughly equipped.

WISCONSIN

Benton.—A new mining company, recently organized, made up of Platteville mining men, is engaged in shaft-sinking on the Calvert land, where lead is making in all three openings. The property will be fully equipped this coming spring.—The McGuire-Stephens mine is equipped for output; carbonate zinc ore at 55 ft. from the surface is opened.

Cuba City.—The National Zinc Ore Separators was supplied with zinc concentrate for November from the Dale, Connecting Link, and North Unity mines. Some high-grade blende was sold in the early part of the month to American Metal Co. Shipments of sulphuric acid, however, have been in fair volume and regular.—The Connecting Link Mining Co. which adhered to regular working schedules through the entire period of depression, used three motor-trucks to haul to the National Separators plant.—The Big Dick mine, owned and operated by the Zinc Hill Mining Co., has been unwatered and is in shape to begin operations.

Livingston.—The Vinegar Hill Zinc Co. is operating steadily and large quantities of zinc concentrate are being shipped to the National Zinc Separators plant at Cuba City.

Mineral Point.—Shipments of oxide zinc from the works of the Mineral Point Zinc Co. continue fair. Both blocks of furnaces are in operation, each block containing 12 double-compartment furnaces.

Platteville.—H. E. Stephens, one of the owners of the

Hlock-House group of zinc-producers has been active in organizing a company for the purpose of exploring veins crossing the city. Impetus has been given to mining in this locality by the opening of the famous Emprise-Enterprise 'range'. It is held by expert field men that this was not the only range in this district, and finds made in sinking wells and in trench-diggings encourage the belief that ore will be found west and south-west of the city.

In the suit of Thomas Dawson v. the Wisconsin Zinc Co., in claim for damages to land and crops from fumes escaping from a zinc-separating plant, operated by the latter at New Diggings, a jury in the circuit court awarded the plaintiff a judgment for \$900. Action was started with claim for damages set at \$1800.

BRITISH COLUMBIA

Alasworth.—Dan McGillis and Al Morrison have uncovered a 1-ft. vein in a tunnel at the Tam O'Shanter group, in the Blondell district. The ore shows free gold; it is estimated to run about \$100 per ton. Last year 56 tons of ore was shipped to Trail from surface workings. The shipment of ore from the Florence mine to the Bunker Hill & Sullivan smelter gave a return of 69.8% lead and 15 oz. silver per ton. Now that a market has been assured for the output, the Florence Silver Mining Co. purposes to increase its milling output. A large body of ore has been developed, the ore occurring in both fissure and replacement veins.

Revelstoke.—While on fire-patrol duty near Halcyon, in the Upper Arrow Lake district, A. Fowler stumbled across what may be an important discovery of lead-zinc ore. Fowler describes the deposit as being 300 ft. wide and traceable for about three miles. With associates he has taken up a number of claims and is taking out a trial shipment. The point of discovery is situated conveniently for shipping.

Rossland.—The return from the two tons of bonanza ore recently shipped to the Bunker Hill smelter from the I. X. L. mine show a yield of 296 oz. of gold and 47.5 oz. of silver, while the 20 tons of second-grade give a return of 4.195 oz. gold and 5.75 oz. silver per ton. The shippers are pleased with the treatment they have received from the Bunker Hill & Sullivan company, which paid for the whole of the gold in the high-grade ore at \$20 per ounce, 96% of the gold in the second-grade ore, and charged \$8 per ton for treatment. This they maintain is an improvement on the Consolidated company's terms. It made a charge of \$100 per ton for treating the bonanza ore and paid for only 95% of the gold content, added to which it absorbed 3% advantage in exchange. The Kellogg smelter paid half cash and half at 30 days in U. S. funds. The bonanza ore is holding out well, being as rich as ever in both the roof of the raise and the floor of the winze. Another shipment will be made in a week or two.

Stewart.—The S. S. 'Anyox', which arrived here recently, brought a large supply of machinery for the Premier mine. It took south a consignment of 250 tons of concentrate from the Premier and a small consignment of high-grade from the Fish Creek mine, both of which went to the Tacoma smelter.—Howard Cameron has been appointed superintendent of the Silverado mine, in place of R. L. Clothier, who resigned recently. Construction work is progressing well, but it will be a race to get the tramway finished before the heavy snow, and on this depends the possibility of shipping ore through the winter.

Trail.—During the last ten days of November 7510 tons of ore was received at the smelter, 7072 tons coming from the Consolidated company's own mines. The other shippers were: Echo, Silverton, 5 tons; Horn Silver, Similkameen, 53; Josie, Rossland, 105; Knob Hill, Republic, 161; Surprise, Republic, 112; and Widowson, Nelson, 2.

JAPAN

Tokyo.—The Yawata Steel Works, in Klusbiu, is now

building a plant to manufacture billets for private steel makers. Dispatches state that the construction program calls for completion of the plant about April 1924, when a productive capacity of 200,000 tons of billets per year is expected.

MEXICO

Chihuahua.—The San Pasqual de las Adargas Mining Co., operating a large group of rich properties in the Adargas mountains, about 15 miles south-west of Jimenez, is going to build a branch railroad line from the camp to Jimenez or Dolores station on the main line of the National Railways of Mexico, for hauling their ores and supplies. Some of the ores from these mines will be shipped to the United States for treatment. The company recently contracted with the Hoquilla Power Co. for the transmission of electric power from its plant at the Boquilla dam to the mines.

El Tigre. T. J. Lawrence and Benito Solls of El Paso, recently denounced the Santa Elena claim, situated about 8 miles south of here; they are engaged in developing the property.

Sacozari.—E. H. Devore has secured a renewal of the lease and bond on the Rubi mine from the owners, Marquard and Castillo. This is believed to be the famous old Juacal

Sacozari, Sonora, from the Moctezuma Copper Co.'s Mill

mine. R. H. Bartlett has been given a contract to sink the shaft to a point 50 ft. below the lowest old workings.

A denouncement has recently been made by R. H. Bartlett of a fraction of ground between the Rubi mine and the Carnaval recently taken up by C. A. Pierce of Patagonia, Arizona. This fraction has the continuation east of the Rubi vein, and has a strong surface showing.

Santa Ana.—George East, manager and owner of the San Jullan and Tres Piedras molybdenum mines in the Sahuaripa district, is contemplating starting work with the flotation plant here. Considerable ore has been milled, and the concentrate averages better than 90%, which makes it a desirable product.

Torreón.—Americans representing New York capitalists have taken over the Reyes smelting plant, situated about 35 miles west of San Juan de Guadalupe in the State of Durango. This smelter was built in 1910 by the Reyes Smelting & Mining Co. but was forced to suspend after a few months on account of the revolution. One car of bullion was shipped. The ores treated were mined from the properties in the vicinity of the smelter, most of which belonged to the company. There is an abundance of good fluxing ores close to hand and at Valenciana, a short distance south-west of the Reyes, in an old slag dump, carrying from 15 to 20 oz. silver per ton. Repair work on the buildings and machinery of the Reyes smelter have been commenced and it will be ready to blow in within a few months. A lease and option has also been taken on a number of the mines in this district by the new company.

ONTARIO

Cobalt.—Production of silver from the Cobalt and surrounding districts during November amounted to 900,000 oz., according to preliminary estimates. The gross value of the output was \$630,000, plus a premium of between 8 and 9% on United States funds. By the close of February, next, at the current rate of production, the value of silver produced from this district since the first discoveries in 1903 will reach \$200,000,000.

The Hudson Bay Mining Co. having curtailed operations on its Cobalt property has completed an examination of the Cane Silver Mines in Cane township in the Elk Lake district with a view toward taking over the controlling interest provided the results of sampling are satisfactory.

A new company is being incorporated for the purpose of operating claims in the Larder Lake district on which the Crown Reserve has recently been carrying on exploration work. The Crown Reserve, Porcupine Crown, and Imperial Crown companies will each contribute to an aggregate fund of \$250,000 with which to equip the property with machinery and carry out exploration and development work, which has been recommended.

Arrangements have been made to sink to deeper levels on the Violet property of the La Rose, so as to operate at the same horizon as that in which the adjoining O'Brien mine is finding large quantities of silver ore.

Kirkland Lake.—The shareholders of the King Kirkland have adopted by-laws increasing the capital of the company from \$2,500,000 to \$5,000,000, and ratifying the purchase of the Ferguson claims adjoining their property. This gives the company a total area of 289 acres through which the government road runs. About 100 acres will be laid out in town lots to provide homes for the miners. Modern mining equipment is being installed.

The mill of the Ontario Kirkland, having a capacity of 100 tons daily, has started producing. The company has sufficient ore in sight to keep it running for three years as development work has opened up 100,000 tons of ore averaging \$15 per ton.

At the Bidgood cross-cutting is in progress on the 400-ft. level to tap the downward continuation of the main vein, which is expected to be reached at a point 40 ft. from the shaft.

Porcupine.—The Nipissing has given up its option on the Edwards property, the results of diamond-drilling being unsatisfactory. Exploration by drilling is being continued on the Rochester, where a sixth hole is being put down. Gold was found in the fifth hole.

The production of gold from the Porcupine and Kirkland Lake districts during November amounted approximately to \$1,505,000. Premium on American funds being about \$120,400; this would bring the total income up to \$1,625,000.

Toronto.—The Order-in-Council issued by the Ontario government extending the time for doing assessment work by returned soldiers until the end of the year will not be renewed. Although no further general extension will be granted veteran claim-owners who find it impossible to perform arrears of assessment work in time may make application for an additional extension setting forth their reasons for relief.

The offices of the International Nickel Co. are being closed, at least temporarily, and executive business transferred to headquarters at New York. A. D. Miles, president of the International Nickel Co. of Canada, the subsidiary company, and other officials have tendered their resignations. This is understood to be due to depression in the nickel industry, which some time since resulted in the closing down of the company's mines and works in Canada.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

J. E. White was at Riverside, California, last week.

James L. Bruce has returned from Spokane to Butte.

C. B. Lakenan is spending a few days at Salt Lake City.

C. N. Schmette has returned to San Francisco from Colorado.

Roy Brown, of Tonopah, is in San Francisco for a few days.

Charles H. White has returned to San Francisco from Nevada.

L. D. Ricketts has returned from Sonora, Mexico, to Warren, Arizona.

Cyrus S. White has moved from Reno, Nevada, to Iowa Hill, California.

W. F. Deister, vice-president of the Deister Machine Co., is in San Francisco.

Robert K. Painter has moved from Stirling, New Jersey, to Auburn, California.

F. F. Mathien is expected in San Francisco from Tientsin, China, early in January.

L. C. Trent is developing the Gooney Manor copper mine near Front Royal in Virginia.

Dan Harrington, engineer for the U. S. Bureau of Mines at Denver, is in San Francisco.

Fernando Montijo, of the Minas Pedrazzini in Sonora, is spending Christmas at Berkeley.

Henry E. Wood passed through San Francisco on his way from Montana to Santa Barbara.

W. R. Wolton is now with the Corocoro United Mines, at Corocoro, Bolivia, South America.

R. L. Agassiz, of Boston, has been elected president of the Copper and Brass Research Association.

Fred G. Farish, of the Metals Exploration Co., has returned from the Comstock to San Francisco.

Harlow D. Phelps has opened offices as mining and civil engineer in the Bashford building, Prescott, Arizona.

Albert Burch has been nominated as chairman of the San Francisco section of the A. I. M. & M. E. for the coming year.

H. L. Payne has returned to Los Angeles from Yuma, Arizona, where he was attending court relative to the fluor-spar controversy.

Charles W. Stimpson, president of the Stimpson Equipment Co., has returned to Salt Lake City after a two months holiday in Honolulu.

R. S. Baverstock, of Baverstock & Payne, has just returned to Los Angeles from the Randsburg district, and will leave this week for Acton, California.

A. W. Stickney, who has been with the Russo-Asiatic Consolidated, Ltd., at Austin Friars, London, is now with the Mines de Boson, at Frejus, in France.

E. M. Rombouts, general manager for the Sarakresk Gold Mining Co., Surinam, Paramaribo, Dutch Guiana, sailed from there on November 11 for Amsterdam.

L. S. Breckon, who recently returned from Cerro de Paseo, Peru, has been appointed general superintendent for the Consolidated Mascot Mines Corporation at Hailey, Idaho.

Thingley S. Wood died in San Francisco on December 9. He was prominent at Leadville in the 'seventies and operated several important mines, including the Silver Cord and Lilian.

The Society of Economic Geologists will hold its second annual meeting at Amherst college on December 28 and two following days.

THE METAL MARKET

METAL PRICES

San Francisco, December 13

Aluminum-dust, cents per pound.....	65
Aluminum-sheets, cents per pound.....	60
Antimony, cents per pound.....	8.25—8.25
Copper, electrolytic, cents per pound.....	14.75—15.25
Lead, pig, cents per pound.....	4.95—5.05
Platinum, pure, per ounce.....	\$78
Platinum, 10% iridium, per ounce.....	\$90
Zinc, slab, cents per pound.....	9.75—7.75
Zinc-dust, cents per pound.....	9.50—10.00

EASTERN METAL MARKET

(By wire from New York)

December 12—Copper is active and strong. Lead is quiet and firm. Zinc is dull but steady.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 48.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

DRAWING ON STORED MEXICAN OIL

Comparison of production and export of oil from Mexico for September showed that many companies are drawing from storage to supply oil for export. Crude-oil in storage is much less than 41,000,000 bbl which represents total capacity, and may be nearer 20,000,000.

'Wild-cattling' is now needed, and much of it is centering south of the Tuxpam river, and in a direct line with Potrero, Cerro Azul, Toteco, and Amatlan fields. Most of this has been started within the last year. Several difficulties previously have stood in the way of this work, including political uncertainties and legal complications.

At least 30 square miles of territory immediately south of Tuxpam river has been acquired by prominent oil companies of Mexico. Most of it has been taken up by companies which have had wells in the older fields. Some of the new acreage is split up into small tracts in the same way that part of the old producing acreage was divided. One lot, Lot 6, on what is known as the Castillo tract, is divided among nine different companies. A well is now being drilled on that tract by the Corona Petroleum Co., a Royal Dutch subsidiary.

With estimated investment of \$425,000,000, approximately 650,000,000 bbl of crude-oil has been taken out and marketed. Estimated investment to the end of 1920 was as follows, according to the Department of Commerce:

Approximately 1000 wells, drilled and producing.....	\$100,000,000
Value of land upon which wells were located.....	50,000,000
Pipe-lines, railroad, and rolling-stock.....	50,000,000
Refineries, machinery, and buildings.....	50,000,000
Miscellaneous producing properties, of which the greater part belongs to Great Britain.....	50,000,000
Oil-tankers.....	125,000,000

Total \$425,000,000

American oil companies have the biggest interest in almost every branch of the industry, the following table showing the percentages:

	American	British	Other
Production.....	66	33	1
Exports.....	84	16	..
Number of tankers in service.....	73	18	9
Tanker tonnage in service.....	75	15	10
Pipe-line, miles.....	66	34	..
Pipe-line capacity.....	88	14	..
Steel storage-capacity.....	40	60	..

MONEY AND EXCHANGE

Foreign quotations on December 13 are as follows:

Sterling, dollars: Cable.....	4.19 1/2
" Demand.....	4.20
Franc, cents: Cable.....	8.20
" Demand.....	8.22
Lira, cents: Demand.....	4.70
Mark, cent: Demand.....	0.50

Eastern Metal Market

New York, December 7.

All the markets reveal a strong tone, higher prices, and a good demand.

Copper prices have advanced about $\frac{1}{2}$ c. per pound and buying and inquiry continue satisfactory.

Buying of Straits tin has again revived and large sales at higher prices are recorded.

The lead market is firmer with a better demand for early shipment.

The zinc market has advanced and the tone is stronger.

Antimony is quiet and inactive.

IRON AND STEEL

The returns of the country's pig-iron output in November indicate plainly that the expansion in steel production in the past two months had made large inroads in pig-iron stocks, compelling the rapid blowing-in of a good many iron-furnaces.

The steel trade is taking great interest in the plans for merging seven important independent companies, representing every form of rolled products except tin-plate. The consolidation would have about 20% of the country's steel capacity, while the Steel Corporation has 45%. The new combine would have a larger share of the country's capacity in plates than in any other product.

COPPER

The feature of the week's development is the estimate that total sales for November were 190,000,000 lb. This is a very heavy movement and contrasts with 140,000,000 lb. for October. It stands as the record for the year and probably will continue so, as December is expected to be quieter. Deliveries into consumption are not yet calculated, but they were probably also heavy and perhaps the heaviest of the year. The market is strong and progressive, with prices higher than a week ago by at least $\frac{1}{2}$ c. per pound. The actual market depends on the seller, some asking higher prices than others. For early or December delivery the minimum for electrolytic copper is 13.50c., refinery or New York, and 13.75c., delivered, and for January or first quarter it is 13.75c., refinery, or 14c., delivered. A small amount might be obtained from certain quarters at $\frac{1}{2}$ c. under these levels. The large producers are all firm at or near the higher levels. Inquiry for both domestic and foreign consumption is excellent, mainly for first quarter, and buying continues entirely satisfactory, with some sellers out of the market for December and January. Sales to foreign countries continue heavy and prices are at least 14c., f.a.s.

Exports of refined copper to November 1 have been 468,215,221 lb., against 479,735,553 lb. to November 1, 1920. Germany is the heavy buyer, being credited with 184,739,354 lb. of this year's outgo, or about 40%.

TIN

A heavy business in Straits tin has again been done. On November 30 and December 1, Wednesday and Thursday of last week, as well as on Saturday and Monday, December 3 and 5, buying was excellent and the market has risen each day. On November 30 and December 1 a good business for all positions was done at above and below 30c. with some business on December 3 at the same levels. On December 5 heavy sales were put through, aggregating 500 to 750 tons, for all positions. This advance and the higher value of sterling have been factors in the market. American pure tin, electrolytic, has sold at 31.50c.

Deliveries into consumption in November were 3250 tons, with 1316 tons in stock and landing on November 30. Im-

ports to December 1 have been 20,668 tons, against 48,093 tons to December 1, last year.

LEAD

There is more strength to the market from an increase in demand for December shipment. While prices are not quotably higher, they are stiffer. The leading interest has not changed its quotation of 4.70c., New York and St. Louis, for early delivery and is still taking business at this level in New York. The independent's prices are higher at 4.75c., New York, or 4.45c., St. Louis, and sales at Eastern points outside of New York have been made at 4.75 to 4.77 $\frac{1}{2}$ c., delivered. Lead in England continues scarce and high and the situation is full of interest on this side.

ZINC

The market is higher, but there is not much activity. There is some demand from galvanizers, who seem to need certain quantities for December consumption, and this, due to somewhat limited supplies available for sale, has caused prices to advance. Sales were made yesterday of small lots at 4.87 $\frac{1}{2}$ to 4.90c., St. Louis, or 5.37 $\frac{1}{2}$ to 5.40c., New York, which is quoted as the market. Production is reported to be on the increase.

ANTIMONY

There is no change to record. Wholesale lots for early delivery are nominal at 4.50c. per pound, New York, duty paid, with spot delivery at 4.55c. Jobbing lots are about $\frac{1}{2}$ c. higher.

ALUMINUM

The leading interest continues to quote virgin metal, 98 to 99% pure, at 19c. f.o.b. plant. The same grade from Sweden, Switzerland, Germany, and other countries is quoted by importers at 17 to 18c., New York, duty paid.

ORES

Tungsten: No developments are recorded. Business is stagnant and prices are largely nominal at \$2 per unit for Chinese ore, with others higher, depending on grade and delivery.

Molybdenum: Nominal quotations are 45 to 50c. per pound of MoS₂ in regular concentrates.

Manganese: There is absolutely no demand, as stocks are large and the production of ferro-manganese is at a standstill. Quotations are nominal at 20c. per unit, Atlantic seaboard.

Chrome: With heavy stocks in consumers' hands there is no demand and quotations are nominal at \$20 to \$28 per net ton, c.i.f. Atlantic ports, depending on grade and other conditions.

FERRO-ALLOYS

Ferro-manganese: More interest is recorded, sales of about 1500 tons being reported. About 1100 tons of this is British and American, mostly American, with the rest sold by the Carnegie Steel Co. Quotations are \$58.35, seaboard basis, for British and Independent American producers, with \$60, Pittsburgh, the price of the Carnegie company.

Spiegeleisen: Sales are confined to a few carload lots at \$25 to \$27, furnace, for the 20% grade. Stocks are declining and no fresh alloy has been made since early in the summer.

Ferro-tungsten: In the absence of activity prices are nominal at 40 to 45c. per pound of contained tungsten for the domestic alloy, with 50c. the quotation for the imported at the seaboard, duty paid.

Ferro-silicon: The market for 50% alloy is quiet but firm at \$60 per ton, delivered.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

COPPER'S IMPORTANCE IN DOMESTIC COMMERCE

By Thomas D. Brophy

*When the 'Santa Maria' arrived off the coast of Honduras, Columbus captured a native canoe, and among other things it contained a number of copper hatchets. After reaching a point near Panama, he wrote a report to his sovereign and, in mentioning the incident, spoke of these and other excellent examples of the Coppersmith's art, adding that he believed the country contained great mines of copper. Almost from that day forward, the mining of copper ores and the fabrication of copper metal have been important factors in the industrial and economic life of our country.

With the discovery of large copper deposits in New Jersey, Pennsylvania, and Virginia, and the establishment of rolling-mills in Boston, New York, and Baltimore, the development of the industry was rapid, and in the middle of the last century we find copper or its alloys in general use for cooking-utensils, roofing, ornamental-ware, and a thousand other uses, ranging from the manufacture of pins to the sheathing of ships. The coppersmith was as necessary to community life as the blacksmith.

With the advent of the great era of electrical development, the demand for copper jumped enormously. The production of the country was totally inadequate, the price rose rapidly, and it became increasingly difficult to secure copper at a price which made possible its use for domestic purposes. Great new copper deposits were discovered, new mines were opened up, improved mining and smelting methods were developed, but still production was inadequate to meet demands.

The situation was further complicated by a series of wars and the consequent demand for copper for munition purposes; by the development of the automobile industry; and by the great extension of interurban electric service. This enormous demand for copper resulted in an increase of production of 1,600,000,000 lb. per annum in ten years.

With the coming of the World War, the demand for copper became so great that its use in all but essential industries was expressly prohibited. Manufacturers were forced to cut out copper wherever possible and the use of the metal for domestic purposes was practically discontinued.

During this ten-year period when practically the entire copper supply was being absorbed in the development of new industries, the old established markets were entirely neglected and hundreds of substitutes were placed on the market, claiming all the virtues of copper, and selling at a considerably lower price. Intensive advertising and intelligent sales promotion work resulted in the successful marketing of these substitutes, notably in the roofing-material field. The kitchen-utensil industry also suffered.

In 1912 the average amount of copper used in automobiles of American manufacture was approximately 200 lb. per car. Today the average is less than 30 lb. per car. In 1914 a large manufacturer of screws, nuts, bolts, etc., in this

country, consumed 10,000,000 lb. of brass. Last year they used less than 3,000,000 pounds.

The superiority of brass pipe, especially for hot water supply, is unquestioned, yet today brass represents only a small percentage of the total outlay for plumbing, even in our finest buildings. The plumbing in the Commodore hotel in New York cost \$900,000, of which only \$3,150 represents brass pipe. The plumbing in the Woolworth building cost \$450,000, of which only \$32,400 went for brass pipe.

In no one industry perhaps has copper and brass lost so heavily as in building, yet most architects prefer to specify copper and brass as a matter of professional pride. A recent canvass of architects in and around New York developed the fact that 137 out of 150 interviewed recommended copper as the best roofing material obtainable, 141 recommended copper for flashing and down-spouts, and 128 recommended the exclusive use of brass pipe. Architects generally would gladly use copper and brass if prospective builders understood the rare and exclusive qualities of the metals and would be willing to bear the extra expense.

Sheet-copper is the best roofing material known, being very light, absolutely impervious to the action of the elements, and practically everlasting. It is capable of being laid flat or being worked to any curve, and after being in use a short time it takes on a most attractive color which harmonizes with practically all building materials. The first cost of copper roofing is greater than that of some other materials, but over a period of years copper, with practically no maintenance cost, is considerably less expensive than any other material, and if a copper roof is properly erected it should last practically forever.

There are thousands of examples of copper roofs in service in all parts of the world. Nagoya Temple in Japan was roofed with copper 510 years ago and is today in perfect condition, and its many gabled roofs, covered with the green patina of age, have taken on added beauty every year. The dome of the State House in Boston was roofed with copper in 1831, and is still in excellent condition after 90 years exposure to the rigors of the New England climate. Christ Church, Philadelphia, has a copper roof laid in 1838, and I was recently informed that there is every reason to believe that the roof is good for another 100 years at least.

There are hundreds of less conspicuous examples of the wisdom of roofing with copper in the older sections of the country. Yet copper is rarely specified today because of a slightly higher initial cost which is saved many times over, even in the first few years of service. For other roofing purposes, such as flashing, gutters, and rain-conductors, copper is unequalled. On the Chew mansion in Germantown, Pennsylvania, one of the conductors bears the date of 1798.

It has been estimated that an average of 400 ft. of gutter and conductor pipe is used on the typical American dwelling. Made of copper, it would cost less than \$200—a small item in the total cost of building a home—yet over 90% of the spouting used is made of galvanized iron, which must be replaced at intervals of not over five years, while

*Abstracted from an address delivered before the American Mining Congress.

copper lasts a lifetime. The cost of erecting copper and galvanized iron is substantially the same and the difference in initial cost is absorbed before the first replacement of galvanized iron is completed.

The use of copper in shipbuilding is as old as the industry itself. The ancients used it extensively and modern ingenuity has devised no better. Paul Jones sheathed the sides of the 'Constitution' with copper in 1803, and the old 'Granite State', having completed 75 years of service in the American Navy, is now about to be burned to the water's edge in order that the charred hulk may be stripped of a copper bottom and the copper spikes in her hull reclaimed.

Lightning-conductors, which we owe to the genius of Franklin, have been given an evil reputation by the machinations of fakirs and confidence men. Yet, the fire losses of this country due to lightning are enormous. The Department of Agriculture is constantly urging the use of lightning-conductors, and fire-insurance companies allow reduced premium rates on buildings so protected. But this great industry has been allowed to languish and become the prey of shysters. Copper as the premier conductor of electricity is the logical lightning-conductor.

Where resistance to corrosion, easy handling of expansion and contraction, absence of upkeep expense, and long life are to be desired, copper is supreme. My purpose is not to detract from the merits of other metals—all have their uses—but there are certain fields in which copper excels and we intend to do all in our power to restore the metal to its former position of dominance.

The automobile industry will return to brass when the buying public is taught to demand quality where it cannot be seen, but counts the most. Copper roofing can be revived if the merits of copper are known. Brass-plated screws can no longer pose as solid brass if the consumer is taught to demand the best.

SIZING SAND

The Allen sand-tank, manufactured by the Allen Cone Co., of El Paso, Texas, is a new form of the sand-cone, especially adapted to washing sand and gravel. The Allen sand-cone has been a standard machine in ore reduction, phosphate-washing, and similar industries for a number of years, and the principles by which it operates have been thoroughly proved. The change to the Allen sand-tank has been one of detail only, adapting it to the heavier tonnages and the rougher usages it has to meet in sand-washing plants. It has important advantages over the older forms of sand-collectors. Its greatest advantage is the simple and positive Allen automatic control. This reliable mechanism for regulating the discharge is not affected by a few pounds of sand in the wrong place, or a slight warping of the supporting timbers, such as will throw the old-fashioned tilting-hox and similar machines entirely out of adjustment. In addition, the adjustment of the Allen control is simple and easily understood, and does not depend upon the careful balancing of a counter-weight.

It has also the new reduction plate, which is a most important improvement over other forms of sand-collectors. The use of this reduction plate is to reduce the area through which the current going to the overflow passes, regulating in this way the amount of fine sand settling in the tank. Provided that the full area of the tank is sufficient to settle the fine as well as the coarse sand, any part of the fine sand may be eliminated by simply moving the reduction plate. In this way the sand is classified, so that its grading may be made to meet any specifications within the limits fixed by the feed to the tank. All sand banks contain dirt and silt in varying degree, and it is rare to find a deposit from which 'run of bank' sand will be accepted by engineers for making concrete. Practically all concrete-sand is washed.

In addition to being washed, sand should be graded. That is, it should have a certain proportion of each size, from the largest that is permissible, say $\frac{1}{2}$ -in., down to the finest permissible. If all the grains are the same size, there will be a much greater percentage of voids than where there is a proper proportion of each mesh-size, for the small grains will fill the spaces between the large grains, and thus reduce the percentage of voids. The more voids in the sand, the more cement must be used, for if these voids are not filled the concrete will be weak. But fine sand, beyond a certain limit, has also the effect of weakening the concrete. Hence the best concrete is made from sand which is graded to have the proper proportion of each size. Engineers claim that three-fourths of the failures of concrete are due to poor sand, and many engineers are insisting that of all the tests that are made, of materials for making concrete, the most important test is that of the sand. Sand may be produced by the Allen sand-tank to meet any reasonable specifications. It cannot, of course, put, say, minus $\frac{1}{2}$ in., plus ten-mesh grains into the sand, if the grains are not there to start with. But if the grains are there, it can modify the proportions of the other sizes to meet the requirements.

Type AN polyphase induction motors, made by the Allis-Chalmers Manufacturing Co., have been well and favorably known for many years. In order, however, to take full advantage of improvements and advances made during recent years, and benefit as far as possible under all conditions of operation, the new line of Type AR motors has been developed. These range in output from $\frac{1}{2}$ to 200 hp. A prominent feature is the use of cast-steel in place of cast-iron wherever practicable. The development of the electric furnace during recent years has made possible the production of high-grade steel castings true to pattern and suitable for use in machines of this kind. The castings are used for the stator end-frames, and rotor-spiders wherever the size of the motor is such as to require a spider to carry the rotor laminations.

A very efficient method of ventilation is used whereby even cooling of the internal parts is secured. This results in temperatures more uniform than in former designs and avoids 'hot spots' which have a deteriorating effect on the stator-coil insulation. High-grade insulation is used throughout. After the winding has been completed and all connections made, the stator is treated with baked-on insulating varnish, which makes the whole structure dust and moisture proof. Rotor-bar end-fastening of squirrel-cage construction generally is such as to stand the most severe conditions without developing defective joints. Bulletin No. 1118 describes these motors fully.

A ditch-blasting test in snow and ice of the new non-freezing straight dynamite manufactured by the Du Pont company was made during the last few days of November, near Wausaukee, Wisconsin. The ditch was blasted by the 'propagated' method and the dynamite was loaded through 8 in. of snow and about one-half inch of ice in wet soil, the temperature of which was 35°F. at the point of the load. Moreover, the dynamite used had been exposed in storage to freezing temperatures for several weeks. The results were absolutely perfect in every respect. The test is regarded as of great importance to users of dynamite for open work during the winter months. Straight dynamite has for years been the standard of the world in nearly every kind of open work, but a disadvantage has been its liability to freeze at temperatures below 50°F. Any dynamite loses part, if not all, of its efficiency when chilled or frozen, and many attempts have been made to make the explosive low-freezing. This test in Wisconsin shows that thawing, with its loss of time and attendant danger, has practically been eliminated.

T. A. RICKARD, . . . Editor

ELECTRICITY is being adopted on an increasing scale in place of steam as motive power for railroads, especially in foreign countries. The latest news in this connection comes from South Africa, reports indicating that the Railway Board has decided to electrify the Durban-Glencoe line at a cost of about \$25,000,000. Changes such as this will serve to popularize electricity and to promote the more extended use of its conductor—copper. The surplus is assured an early extinction.

IN our issue of December 3, on page 776, a tabulation of new flotation plants contains the erroneous statement that grinding in the remodeled Nevada Consolidated concentrator is to be done in Marcy ball-mills; likewise the flow-sheet on page 778 shows the same error. As explained on page 775, the statement and flow-sheet refer to Section 4, the most recently remodeled of the eight sections in the plant. The fact is that the mills in Section 4 were made by the Power & Mining Machinery Co. and are not Marcy mills. It is also fair to say that Section 3, remodeled a year ago, contains Hardinge ball-mills exclusively, and that the design for re-building the remaining sections for the use of flotation specifies Hardinge ball-mills.

H. G. WELLS has a virile character, as is shown by his refusal to write under dictation. He came to Washington as a representative of the London 'Daily Mail', one of Northcliffe's strident chorus. His criticism of French policy displeased his employer and he was instructed to abate his impetuosity. He resigned; whereupon the 'Mail' showed characteristic lack of taste in publishing the confidential correspondence between them. This did not close the incident, for the New York 'World', which had the first right of publication to the Wells articles, reprimanded the 'Mail' and stated that the news columns of the 'World' "had no policy except the publication of the truth". We do not like the 'World', partly on account of a Pulitzer prejudice, but we do like that statement immensely. It asserts an idea fundamental to true journalism. Mr. Wells comes out of the affair with credit.

GENERAL DAWES, known as the Budget chief, states that among the numerous suggestions sent to him, for the furthering of Federal economy, was one from a Western farmer, who said: "Abolish all these stenog-

rapher jobs and make the highbrows take most of their own dictation. There's too much letter-writing anyhow". He may have been a farmer, and the farmer is too often accepted as a synonym for ignorance of large affairs, but we find much sense in this idea. The ease with which a letter can be dictated to a stenographer is the cause of much needless letter-writing. That needs no argument. Moreover, the gentlemen in the Federal employ, as well as those employed by corporations, would save much paper, and much time at the terminals of their correspondence, if they would do more of their writing themselves in long-hand, for that is the only way to learn to write tersely and clearly.

ENGINEERS and capitalists who are interested in the resources of the mountainous districts of northern Chihuahua will be interested to learn that the Kansas City, Mexico & Orient Railroad Company's line between Kansas City and Topolobampo, on the Gulf of California, will be completed in the near future. At the present time two unfinished gaps remain in Mexico—one between Fuerte and Sanchez, a distance of 155 miles, the other between Alpine and Palomir, approximately 158 miles. We learn from a consular report that the British financial group in control of the line is ready to begin construction. Labor is cheap and plentiful, and the work will have the unqualified approval of the Mexican authorities, for it will give employment to a considerable number of men. The Government is also said to desire the completion of the road, so that there may be ready access to the north-west territory of the Republic. The work will probably take about three years and when completed will facilitate the development of a region that is now almost inaccessible, but that has been and will doubtless be among the richest mineral areas in Mexico. A number of well-known mines will be brought into closer touch with the outside world. These include the Palmarajo, the Batopilas, the Rio Plata, and the Lluvia de Oro properties in the State of Chihuahua, and the El Fuerte company's holdings in Sinaloa. In each case mining operations have been handicapped by a lack of transportation facilities.

CANADA is rapidly improving her position as a producer of gold. Production began in the Poreupine district in 1910 with bullion valued at \$35,529. In 1914 the output was worth \$5,190,794; in 1920, \$11,862,237.

The Department of Mines anticipates that the production for 1921 will show an increase of about \$2,000,000 over that of 1920. The Hollinger is crushing about 3300 tons per day for a yield valued at nearly \$1,000,000 per month. The McIntyre has added to its crushing and treatment plant, it has solved difficulties in the metallurgic treatment of the ore, and it will improve the results of last year, when gold valued at over \$2,000,000 was produced. Interesting and profitable developments have occurred in the lowest levels of the Dome mine, and this presages an increased output of gold in the near future. The Keeley mine is in bonanza. Four mines in the Kirkland Lake district produced bullion that was valued at over \$500,000 during the first six months of this year. The Department estimates an annual yield approximating \$25,000,000 from the mines in Northern Ontario in the near future. In Canada and elsewhere there is more optimism about gold mining than there is in any other branch of the mineral industry. Improvements in conditions must be sought and encouraged, not merely anticipated. Much is being done; but more is possible by a recognition of the benefits of metallurgic research and by the adoption of ambitious schemes of treatment.

AT a time when our people are foregathering for Christmas festivities and rejoicing in a happier outlook, political and economic, it may be timely to remind them of the less fortunate fate of other peoples. In a letter from a distinguished mining engineer we have been given sundry details concerning conditions at a well-known copper mine in Russia. The mine is the Atbasar, which is situated in a part of Siberia populated by the Kirghiz, a Tartar race. Recently they revolted against the Soviet government. A Red army was sent against them and subdued them in short order, because they have no weapons save lances. The Russians cut the bodies of the killed into pieces and scattered them over the steppes. Of the employees at the Atbasar mine, 38 were shot. An English member of the staff, named Yardley, was taken away on a cart with a sick Kirghiz and transported 400 miles to a verminous prison, where he had to await trial as a spy. When nearly starved to death, three months later, he was taken to Tashkent for medical treatment. From there he escaped to Moscow. It is stated that both the Kirghiz employees and the Russian work-people have remained loyal to the Atbasar company; they have taken good care of the machinery and stores, despite the fact that their own needs were pressing. Our informant tells us that trading has begun in Moscow and, although prices are high, there are signs of a resumption of industry. Swedish and German products are much in evidence. The Russians are beginning to exert themselves in the right way. This is typified by the story of the cab-driver who said: "Look at my horse, doesn't he look fine? I feed him *now* and groom him well". On being asked the significance of the "now", he replied: "Formerly the horses belonged to the Soviet; who wanted to feed or groom a Soviet horse?" The moral is that Russia has been a Soviet horse, starved

and whipped, instead of being fed and groomed. We join with our informant in hoping that Russia may be on the eve of a better day.

DOES platinum really exist in the lodes traversing the newly organized Platinum mining district near Winnemucca, in Nevada, or is the district parading under false colors? It has been given a precious name, but is the name deserved? Mr. L. E. Sowers, who, according to a press dispatch from Winnemucca, is chief chemist for the Silver State Chemical Company, insists that he has proved conclusively that sundry rocks in the vicinity contain platinum. On the other hand, Messrs. W. G. Adamson and L. G. Hubbard, local assayers, and Mr. S. C. Lind, of the Experiment Station of the U. S. Bureau of Mines at Reno, maintain that if there be any platinum it is in such form that it eludes the traps that they set for detecting and apprehending it; in short, their analyses proved that the samples did not contain platinum. Apparently it has been charged, or at least insinuated, that 'salting' had been done by somebody, for the press dispatch says that "Sowers especially resents the intimation made by a number of persons that the discovery had been salted". We share Mr. Sowers' indignation; on the face of it the evidence refutes the charge. We have enough regard for the ability of the assayers who failed to find platinum to conclude that there had been no general salting. At the same time doubt rises in our mind as to the technical efficiency of Mr. Sowers' methods of analysis. Again the evidence is in the news itself, in the form of assertions credited to Mr. Sowers. He is quoted as saying that frequently "eminent assayers and engineers have been unable to make platinum determinations from samples actually containing the metal". We demur, respectfully. Quoting further, "Upon completion of the assays I obtained a small button of platinum, and am willing to stake my professional reputation upon the result". This implies the making of a straight fire-assay, which is distinctly not a dependable method of analyzing an ore for platinum. The approved procedure is to combine a fire-assay with a chemical determination. This is accomplished by adding to the crucible in which fusion of the sample is performed a quantity of silver 30 or 40 times as great as the highest suspected content of platinum—its presence is more often suspected than expected. This permits successful cupellation of the lead button, thereby leaving the platinum in the resulting silver bead. A wet or chemical analysis of the bead is then made to determine the quantity of platinum it contains, if there be any; generally there is none. The advantage of the combination method over direct treatment of the ore by wet analysis lies in the fact that an assay-ton or nearly 30 grammes of the pulp can be used, whereas one gramme is the most pulp that is practicable for a wet analysis in which the ore itself is dissolved by acids. It would be a pleasure to record proof of the discovery of platinum near Winnemucca, or anywhere else in the United States, but the preponderance of evidence so far is against Mr. Sowers.

A Christmas Greeting

If we compare conditions now with conditions as they were this time last year, and if we look back to the dark days of Christmas 1917, we shall feel not only happy but uplifted by a sense of restoration. The world has gone through pain and travail for seven long years; during this time it has seemed as if the powers of evil were increasingly in the ascendant, and as if our ideals of human kindness and goodwill were shattered irretrievably. From that darkness we have emerged. Bethlehem in Pennsylvania with its associations of death-dealing implements and coarse profiteering recedes before Bethlehem in Galilee with the old hopes and dreams of peace on earth and goodwill to men. The noise of the shell-makers and the fumes of the explosives plants no longer fill the air with nightmares of hate and horror; the angel voices can be heard in the stillness of evening and a star shines as of old in the heavens from which but lately aerial navies dropped a ghastly dew. We have reached no millennium; man is still selfish and belligerent, but we have learned our bitter lesson: that fighting between the peoples hurts all of them, even the victor; and that killing of human beings by the million at the behest of a few unscrupulous leaders of men is a sure way to the suicide of our civilization. For the peace in Ireland we are grateful, because the conditions there for many years have menaced the goodwill between the English-speaking peoples, upon whom at this stage of the world's history has devolved the lead in re-organizing industry and in restoring that cheerful sanity without which life is impossible. For the friendly agreement made between the nations represented at the Washington Conference and for the first steps toward disarmament we are greatly thankful, believing that these happenings mark the ascent of man to a higher level of intelligence. We have reason to be proud that our country has taken the lead in these matters and that postponement and publicity have been accepted as essentials to the preventing of extremes of misunderstanding such as lead to the arbitrament of war. Much remains to be done, but a start has been made in the right direction, so that we may face the future with a good heart. This year, for the first time in many years, with sincerity and hope we can wish our friends all over the world a Merry Christmas.

The Star Case

A suit arising from a contest for the ownership of the Star mine is engaging the interest of the mining community in the North-West. The Star is a mine near Mullan in the Coeur d'Alene region; it is close to the Hecla mine, the owners of which co-operated with the Bunker Hill & Sullivan company in acquiring the Star, which, in turn, adjoins the Morning mine, owned by the Federal Mining & Smelting Company, a subsidiary of the American Smelting & Refining Company. The Hecla company at one time sent its lead ore to the East Helena smelter, under contract with the 'A. S. & R.', as the Guggenheim company is usually designated; therefore the

partnership of the Hecla and Bunker Hill companies in this venture is a menace to the A. S. & R., because it portends the continued diversion of the Hecla ore to the Bunker Hill smelter at Kellogg, only 16 miles from Mullan, to which smelter it has been going for the last four years. The litigation started four years ago; in 1916 some of the Star shareholders began to suspect that the lower levels of the Morning mine had penetrated into Star ground and that ore belonging to their company was being removed by the Federal company. Whereupon these shareholders started negotiations with the Bunker Hill management for a loan to be used in protecting themselves against the depredation of the Federal company. The Bunker Hill management agreed to make the loan, if granted an option to purchase the Star property. This arrangement having been consummated, the Star company brought suit against the Federal company. The suit went through the courts and terminated in the U. S. Supreme Court, with final decision in favor of the Star company. An accounting for the ore removed by the trespassers has recently been in progress. In course of these proceedings the question of smelting-rates was ventilated, the Star company claiming that the net value of the ore wrongfully removed should be appraised on the basis of fair rates, and not on those paid by the Federal company, the owners of the Morning, to the A. S. & R. company, which, as stated previously, controls the Federal. Next, the Bunker Hill management negotiated for an extension of time to purchase the Star mine. This extension was obtained in December 1920. Later the Bunker Hill company in turn sold part of its purchase rights to the Hecla company, this deal being made for the purpose of securing an entrance into the Star property through the 2000-foot level of the Hecla mine. In making this deal the Hecla insisted upon a 50% ownership in the Star, to which the Bunker Hill assented. Employees of the Federal company have been endeavoring to break this deal, alleging that the Star property is worthless and that the co-ownership was effected by misrepresentation. In this connection it is of interest to learn that the accounting case has just been settled by the payment of \$350,000 by the Federal company to the Star company on account of the profits on the ore extracted from the Star ground. The mine-maps show that the Morning stopes are in ore up to the Star line and across it into Star ground, and it is a fact that the outcrop of the Star lode has been traced for a length of 2400 feet along the surface and also in shallow workings. Here we may state that the chief report on the Star was made by Mr. Oscar H. Hershey, whose ability and integrity cannot be questioned. The completion of the cross-cut from the Hecla into the Star, on the 2000-foot level, will open the Star mine to a depth of 3500 feet and will give both properties direct access to the tracks of two railroad systems, one of which connects with the Bunker Hill smelter. It is against this consummation of Bunker Hill policy that two of the Hecla shareholders have brought suit, with Federal assistance, it being obvious that the good understanding now established between the Hecla and Bunker Hill

companies will be a blow to the business of the A. S. & R. in the Coeur d'Alene. The claim is made, in the suit now pending, that the Hecla directors were misled by the Bunker Hill management. However, in the course of the recent hearing, at Spokane, each director testified that he had obtained independent information concerning the value of the Star property and showed himself qualified to form an intelligent opinion on the matter. It was shown also that the deal was no hole-in-the-corner affair, but one that had been discussed frankly and openly for more than a year, and that the Star property itself had been the subject of court proceedings three years ago in the town of Wallace, which is only four or five miles from the mine. One of the reasons given for depreciating the Star is because of the zinc in the ore, it being asserted that zinc as a metal of commerce has no future; and this is said despite the fact, made clear by the Harvard Committee on Economic Research, that for 17 years before the War the price of zinc rose on an average 1.43% per annum, whereas that of pig-iron and copper declined. We may add that we know the president of the Hecla company, Mr. James F. McCarthy, and we have good reason to believe that he is the last man to be hocus-focussed or to lend himself to any tergiversation. The Hecla shaft is in hard rock and is well equipped. The cross-cut from the Hecla shaft to the Star is advancing at the rate of 15 feet daily, and more than a quarter of the entire distance (8000 feet) has been covered. It is to the interest of the mining industry in the Coeur d'Alene that the project be brought to fruition. The hearing of the case was interrupted on November 25 by the illness of the Judge; it will be resumed on January 16, 1922.

Ball-Milling

Ball-milling, like other phases of metallurgical operations, may be successful or it may be unsuccessful. Some writers of articles give the impression that the machinery runs without a hitch; others include a frank statement of failures and disappointments, giving reasons and opinions in place of the customary recital of facts. Having been concerned at various times with the operation of recalcitrant machinery and the treatment of refractory ore, we are inclined to look with favor upon the latter type of engineer, for his attitude indicates a desire to describe conditions as they are, not always as one would like them to be. In the latter class we include Mr. Fernando Benitez, the first installment of whose article on ball-milling and flotation in Chile appears in another part of this issue. Mr. Benitez describes much that will be of interest to metallurgical engineers and ore-dressers; his comments will provide food for thought and discussion. We appreciate the fact that trouble arose from the operation of a combination of the front halves of two Ferraris ball-mills, especially because the tires of the composite machine could not be turned true after being assembled. Mills of this design, in which the weight is carried on tire-and-roller bearings, often have given trouble, usually on account of the position of the supports below the centre-line of the

apparatus and the difficulty experienced in keeping them clean. Nevertheless, this type of bearing has proved to be satisfactory elsewhere, especially if a slow speed be practicable. The compromise made by the manufacturers of the Marcy mill—a tire-and-roller support at one end and a trunnion-bearing support at the other—is not wholly new; a somewhat similar combination was adopted by Krupps for the design of tube-mills many years ago, and may not have been original with them. The tire-and-roller support was arranged at the discharge end, and permitted the use of a screen of large diameter. This facilitated entry into the interior of the mill without removal of one of the man-hole doors, which is usually a difficult operation. It also made possible the prompt discharge of pieces of ground or broken pebbles that had been reduced in size to such extent that they were of no further use in the mill, but rather a hindrance to the efficient reduction of the ore. Some difficulties in the operation of the machine arose from the cause mentioned by Mr. Benitez. Moreover, the pulp could not be maintained at the proper height. The level of discharge, almost at the periphery, resulted in the prompt drainage of the pulp in the mill, with the result that the pebbles at the discharge-end had little to do, and so wore against one another. Mr. Benitez compliments the manufacturers of the Hardinge conical mill on the mechanical perfection of the machine and the efficiency of its operation; he likewise comments favorably on the Allis-Chalmers granulator, but he questions the need for the variable-discharge diaphragm, arguing that the level of the pulp in the mill can be regulated by modifying the moisture content; but would the degree of moisture required to keep the pulp at the proper level, with all the plugs removed, be the amount that would invariably ensure a high grinding efficiency? The question of liner-bolts is also discussed, thereby reminding us of early experiences, when we neglected to operate a newly-erected mill, without ore, for a sufficient length of time to ensure the smoothing of rough edges on the surfaces of bolts and liners. This practice permits adequate tightening before regular operation with a gritty pulp is commenced, for otherwise the sand works its way between liner and shell and so aids leakage. We like the type of liner-bolt favored by Mr. Benitez; it might be adopted more generally. Interesting comments are made anent the effect of varying the capacity of ball-mills by altering the size of the feed. The remarks on the use of the Symons disc-crusher are pertinent, for it was observed that long, flat, and slaty pieces of ore were produced; these were easier to crush in the ball-mill than were the more eubic pieces produced by the jaw-crusher. This, by the way, is one of the reasons why the product of a disc-crusher is suitable for leaching; a proportionately greater surface of ore is exposed in the form of pieces of large surficial area. Percolation is not hindered by the presence of an excess of slime that results from undue comminution and hindered discharge; the extraction of the soluble is at a maximum because of the availability of the material to be dissolved.

DISCUSSION

A Correction

The Editor:

Sir—I note on page 777 of your issue of December 3 the name of the designer of the Boston-Montana mill is given as H. S. Gieser. This is an error, as Mr. Gieser is mill superintendent for the company, whereas O. B. Hofstrand, of Salt Lake City, is the designer of this plant.

E. SHORES.

Salt Lake City, December 3.

[Since receiving Mr. Shores' letter we have also had a letter from Mr. Gieser requesting that a correction to this effect be published. We regret the error exceedingly. EDITOR.]

Russian Placer Mining

The Editor:

Sir—Mr. R. S. Botsford's letter in your issue of May 14 set me in a state of perplexity from beginning to end, as he misinterpreted all the passages in my articles that provoked his rebuttal.

To start with, Mr. Botsford maintains I am wrong in stating that want of capital is responsible for the adoption in Russian placer mining of a hand-to-mouth policy. Such policy is not typical of Russia alone, but is adopted in every branch of industry, all over the world, where there is need of recovering expenses as quickly as possible, and this need is an inevitable consequence of the lack of working capital. Contrary to this elementary economic rule, Mr. Botsford affirms that I have misplaced cause and effect, and that "it is the lack of adequate prospected reserves that causes capital to be withheld". Does Mr. Botsford really think prospecting costs nothing, and that the ascertainment of adequate reserves sufficient to warrant a costly plant—a dredge, for example—can be done without expenditure of capital? Mr. Botsford judges the financial position of Russian placer mining from his work at Nicolo Pavda, and a visit to the Lenskoie property. These two concerns are not at all representative of Russian placer undertakings, as they were both in exceptional financial conditions. The former concern had just been founded at the time Mr. Botsford took up the work at Nicolo Pavda, and, therefore, the company had all its paid-up capital free at its disposal to start operations, while the Lenskoie company was supported by strong financial groups. In opposition to these two companies are all the other placer-mining enterprises in Russia, the majority of which are individual undertakings, or partnerships, without any financial backing.

The other existing stock companies, about a dozen in all, are struggling against chronic financial troubles. Mr. Botsford, evidently, confounded two things: the foreign capital looking for investment in Russian placer mines, and the working capital the existing placer undertakings have at their disposal. In my article I had, obviously, the latter in view, and it will take Mr. Botsford many years more work in Russia before he can get a clear insight in the economic and financial position of Russian placer mining.

Entering into a lengthy explanation of the advantages of proper prospecting, Mr. Botsford forces an open door. Extensive prospecting has been done on the Lenskoie property long before Mr. Botsford visited it, and the 29 Keystone drills in possession of the company are a proof thereof. We all know the value of "proper prospecting", but however useful prospecting data together "with the other necessary data" may prove in dispelling ignorance of local conditions, they can only present suggestions as to the best means for overcoming difficulties of transport; they do not eliminate them, nor solve the transportation problem itself. As I said plainly (page 458), the Lenskoie company has the alternative of organizing an expedition to the mouth of the Lena river, or of transportation over the inland route. The latter means shipping the dredge from America to Nikolaievsk at the mouth of the Amur, and there transferring into vessels to be towed up the Amur river, some 2500 miles, to Stretensk, with probable trans-shipment on the way into vessels of smaller draught, on account of the numerous bars and low water-level on the Shilka in the latter part of the journey, a distance of some 800 miles. At Stretensk there will be another transfer into railway-cars for Irkutsk, and there a transfer to motor-trucks and horse-sleighs to transport to Zhigalovo (250 miles). At this point the dredge goes into river steamers and barges for Bodaibo, and finally it is transferred into railway-cars that take it to the mines. Altogether seven times (unloading at the mines included) handling some 2500 tons of bulky machinery; and it is to be noted that none of the transloading places within Russian territory is properly equipped with cranes or other lifting appliances, and that the construction of the vessels on the Lena (and probably of those plying on the Amur) has to be changed, as all these vessels are destined mainly for transportation of dry substances (flour, oats, etc.) and are not suited for shipment of bulky goods. Moreover, the inland transportation from Irkutsk to Zhigalovo will require the reconstruction and reinforcement of all bridges on this road, and if transportation is intended

during summer time with motor-lorries, a fundamental repair of the road itself is indispensable, especially on the approaches to the Lena river, where considerable blasting will be necessary, as in many places the road is jammed between the edge of the water and high vertical cliffs, and is so narrow that two *tarantasses* (*tarantass* is the Russian three-horse coach) with a gauge about 3½ feet cannot pass abreast.

Vladivostok as a landing port, or the route through Petrograd or Libau, or other Baltic port, and thence by Trans-Siberian railway to Irkutsk, will hardly be more advantageous, as, although it obviates the repeated transfers to some extent, the freight is higher than by way of the Amur river, and the most difficult part of the transportation, from Irkutsk to the mines, remains the same. On the other hand, the voyage to the mouth of the Lena over the Arctic Ocean, although it has been done a few times by special expeditions, is not a commercial route, and the freight and insurance will be very heavy, if there be an insurance company that is willing to run the risk at all. Taking the above into account, I think everybody will agree with me that the transportation to the Lenskoie property of a 17-ft. close-connected Bucyrus dredge has all the characteristics of an "experiment", that is, to put to the proof if within reasonable limits of time and money machinery as heavy and bulky as a 17-ft. close-connected bucket-dredge can be taken to such a remote place. It is easy "to forget the cost for a moment, and think of the profit", but in this particular case it will be wiser to think of the profit when the dredge is safe and on the spot. In any case, no other Russian placer-mining concern, except the Lenskoie company, was financially strong enough to undertake such a transportation problem, the solution of which implies an expenditure of four to five million gold rubles, that is, an amount equal to the cost of the dredge, as pointed out in my article, which on the question of transportation in Siberia does not give occasion to one-sided conclusions, and I regret Mr. Botsford did not interpret my meaning correctly.

As to the working of the dredge in question, I am less optimistic than Mr. Botsford, having had good opportunity to examine closely the ground that it is proposed to dredge, as on my arrival at the Lenskoie mines drifting was going on in the area to which Mr. Botsford alludes. This area was not "abandoned as unprofitable by hand-work", as stated by Mr. Botsford. It could be drifted with the same normal profit as the other areas under exploitation, but I considered it bad policy to mine ground soaked with water at heavy expense for pumping (about 300 rubles per day) when free drainage was obtainable in a year or two, in consequence of the advance of the underground workings a little farther downstream, and the ground could then be drifted at considerably smaller cost. Therefore, one of the first dispositions I made, when I took up the direction of the Lenskoie mines, was temporarily to stop drifting operations in the area in question, and intensify the work on the other drift-mines instead.

The thickness of the alluvium in this portion of the

Bodaibo valley is from 80 to 100 ft., and permanently frozen layers and bodies of lenticular shape occur. The coarse gold lies directly on the bedrock, which is very uneven, the cavities being often so small that owing to the sag of the bucket-line the buckets cannot get at the richest gravel concentrated at the bottom of these poekets, unless the bedrock is broken up to a sufficient depth. It is doubtful whether this can be done successfully, that is, economically, the schistose bedrock dipping downstream, and presenting a hard smooth surface difficult to attack. In wide flats and flood-planes with such bedrock the dredges can work in a direction downstream, so as to break up the schist from the edge, but this is not advisable in a comparatively narrow valley like that of the Bodaibo, particularly in the portion proposed for dredging, where frequent impetuous floods would endanger the dredge, and run it aground each time, carrying the tailing under the boat.

Mr. Botsford contends that all the conditions adverse to dredging on the Lenskoie mines will "not cause insurmountable difficulties". I agree with him, that in the present stage of engineering no difficulties are insurmountable, from a technical point of view, but in mining as a business the crux of the question is the money side of it, as so saliently set forth in H. Foster Bain's excellent address delivered before the Michigan College of Mines.* Under the conditions described there are far more chances against a success in dredging at the Lenskoie mines than for it.

This, obviously, does not mean that I am against the use of dredges in placer mining in general, otherwise I would not have introduced this method in Russia even before gold-dredging was established in America, but I do not consider dredging a panacea, the application of which will make every placer mine a profitable enterprise. I remember well the decision of the Second All-Russian Congress of gold and platinum miners in 1915, having been elected chairman of the Technical Section, regarding the great number of dredges wanted for placer mining in Russia, but I also remember that more gold has been dug into the ground by dredges than out of it, and, I think, every mining engineer should keep in mind the advice given to our young friends by Mr. Bain in the address above-mentioned, that "it is frequently good mining practice, to indulge in what is bad engineering practice".

I can find no explanation as to how my article could give an excuse for Mr. Botsford's insinuation that I do not favor modern labor-saving methods, dredges included. So far as the Nicolo Pavda dredges are concerned, I may inform Mr. Botsford that in November 1912, shortly before my departure for the Lena, I. A. Losieff, co-partner in the Nicolo Pavda estate and founder of the company which then undertook its exploitation, and whom Mr. Botsford knows very well, invited me to give my opinion before the board of directors of the newly founded company, as to what methods

*"M. & S. P.", May 7, 1921.

of working the placer deposits of the property should be adopted. I strongly advocated dredging, and I have every reason to suppose that my advice was not without influence on the decision to place the dredges at Nicolo Pavda. I did not, of course, determine the type of dredge, nor whether the driving power should be electricity or steam, as a decisive opinion in this respect required careful investigation of the entire set of conditions, but I am certainly in sympathy with the choice of the former, the more so that it was planned to install a number of dredges, and erect a common power-plant close to the working-areas. It is to be regretted that owing to *force majeure* this plan could not be carried out to its full extent, and the company had to be satisfied with a mixed installation of only one electric and one steam dredge, which in no way leads to economical operations.

As to the work of these two dredges, Mr. Botsford pretends that the comparison of the results obtained offers a convincing proof in favor of the general use of electric dredges. In fact, Mr. Botsford compares the performance of a modern dredge, I suppose one of the last ones built in America, and designed according to up-to-date experience in gold-dredging, with that of a boat the drawings of which go more than fifteen years back, when they were secured from the Bucyrus company by the Putiloff works (Petrograd), which have manufactured in all some ten dredges of this obsolete design, without introducing any noteworthy change or improvement. It is evident that under such circumstances there cannot possibly be comparison as to the superiority of one driving power against the other, much less a "direct comparison", as Mr. Botsford contends. The digging apparatus on the Putiloff boats is satisfactory; but that the 5½-ft. steam-dredge was digging just half the yardage of the 7½-ft. electric one can only be attributed to serious defects in the steam-plant of the former, the yardage having nothing to do with the nature of the driving power, as fully explained in my contribution to your issue of October 1. That serious defects really existed in the power-plant of the steam-dredge is proved by its quite abnormal consumption of fuel. I saw the Putiloff dredges at work on the Iydel river (Northern Ural) and at the mines of the Compagnie Anonyme de Platine, a neighbor of the Schouvaloff property, and later, in 1911, when the installation of one more dredge on the latter was contemplated, I refused flatly even to consider the acquisition of a dredge that the Putiloff Works offered for sale. It is likely that this same boat was acquired later by the Nicolo Pavda. For the rest, Mr. Botsford seems to over-estimate the performance of the dredges at Nicolo Pavda, especially the electric one, ascribing to it the main portion of the huge dividends of eight million gold rubles declared and paid in 1917. Fortunately, he gives the data necessary to verify his judgment. The electric dredge, Mr. Botsford states, digged regularly 3000 yards of 32c. ground at a cost of 8c. per cubic yard. Taking 120 days of effective work, which is about the maximum at Kytlim (Northern Ural), the profit made

by the electric dredge amounted to some 200,000 rubles, and, say, half as much by the steam-dredge, altogether, say, 300,000 rubles, while "the assistance given to this result by a paper factory and sale of wood" is manifested by a profit of 7,700,000 gold rubles. A generous "assistance" indeed.

The exaggerated importance that Mr. Botsford attributes to dredging at Nicolo Pavda is partly due to incorrect information as to the work previously done on the property. My connection with Nicolo Pavda was a very short one (about 11 months) at a time when I was managing the Schouvaloff mines, not before leaving for them, as stated by Mr. Botsford. The then proprietor of the Nicolo Pavda estate, A. Vorobieff, seeing that the Schouvaloff mines, which during a number of previous years had given an annual loss of some 200,000 to 300,000 rubles, were within one year converted into an enterprise subsequently yielding yearly twice as much profit† by the methods applied by me, and so disdainfully discarded by Mr. Botsford, asked me to act as consulting engineer, and supervise the placer-mining operations at Kytlim. I was handicapped, however, as soon became evident, by the owner being more interested in the exploitation of the forests than in the working of the platinum placers. I saw that little could be done, and, therefore, when my suggestions were wilfully ignored, the result being a break-down causing a delay of six weeks at the very heart of the operating season, I resigned. The bedrock tunnel to which Mr. Botsford alludes was not started by me; on the contrary, I stopped this work, as it was not justified, having been initiated previously on account of the results of a solitary prospecting pit, sunk by one of the former local managers. These details, I admit, are hardly of interest to your readers, but I wish Mr. Botsford, next time, would base his criticism of a personal nature on exact information.

In conclusion, I emphasize that nowhere in the course of my articles do I set "light" dredges in opposition to American, or Californian ones, because the term "light" conveys the idea of a lack of strength, and does not indicate the peculiarities of design. I consider the only proper terminology to be 'close-connected', or 'Californian', type in contrast with the open-connected, or 'New Zealand', type. The latter are not necessarily light dredges.

Wetting and Amalgamation

The Editor:

Sir—Mr. Dolbear's query in your issue of November 12 raises an interesting question. If it is meant that in treating any ore containing gold, the mercury would attach itself to the gold in preference to any other metals present, there is some analogy, since in flotation oil selects metallic minerals in preference to any gangue matter. But if the view is held that mercury attaches itself to

†In the years 1910 to 1912, when the price of platinum increased, the net profit reached 1,400,000 gold rubles.

gold as oil does to a mineral, then I should hold the contrary.

An amalgam is an alloy of quicksilver, a liquid metal, with a solid metal, generally gold. This alloy is solid—that is, plastic—or liquid according to the quantity of mercury present. The gold is actually dissolved, and there are three stages in this action, namely, (1) coating, (2) penetration, and (3) solution. What might be termed the 'pores' of the gold absorb quicksilver to saturation point, after which follows a breaking up of the particles, then their solution. Factors in this process are size of gold, freedom from any coating that might prevent or hinder amalgamation, and time. Some coarse gold, unless ground by some means, never really goes into solution in quicksilver, but it is more or less penetrated by the latter. The change is not chemical, nor is it mechanical, but it might be termed physico-chemical. The structure of the gold is changed by ordinary mortar-box and plate-amalgamation, although it would appear that flaky gold from placers and dredges assumes more or less its original form after retorting, yet it has been penetrated by the quicksilver (perhaps Charles Janin, C. W. Gardner (Yuba), and L. D. Hopfield (Natomas) could enlighten us on this point).

Take the exceedingly fine gold contained in the Alaska Treadwell, Homestake, and Rand ores: although this is rarely visible to the eye, mercury catches it with ease and dissolves it. After retorting, this or any other mill-gold appears as a homogeneous mass, naturally more or less porous.

When mercury is applied to a copper plate, it first coats and then penetrates, as is well known to all mill-men. In doing this, it also carries some gold into the plate.

To prove my statements, Messrs. Thissen and Voorhees amalgamated some fine and coarse gold. The amalgam was squeezed, and that from the fine gold was observed under the microscope. At first the individual grains could be detected coated with mercury, but in time these grains assumed a globular form, showing that the quicksilver was dissolving the gold. A piece of amalgamated coarse gold was broken, and the microscope clearly showed penetration of the gold by the mercury. The excess quicksilver after squeezing out amalgam was then retorted in a flat porcelain dish. This is where the microscope proved whether gold was merely coated or dissolved by quicksilver, and showed that the gold was no longer in granular form, but clearly precipitated from solution. This, I take it, is proof.

In flotation, the sulphides of an ore are wetted by oil and are thereby separated from the gangue, and the resultant product is simply a mechanical mixture of oil and minerals. Oil has no dissolving effect whatever on metallic minerals. It simply coats the sulphides, but does not penetrate them as quicksilver does. Oil can be separated from the collected minerals, leaving them behind, but gold cannot be separated from mercury except by retorting the amalgam.

M. W. VON BERNEWITZ.

Pittsburgh, November 17.

McFadden Bill

The Editor:

Sir—In your issue of November 26, commenting on a letter from S. J. Kidder, you refer to the unfairness of the practice of the United States Mint in selling gold at a price far below the cost of production, as being comparable with that which the 'M. & S. P.' suffers by reason of the unduly high cost of paper. Surely you would not seriously maintain the two things to be comparable? The injustice to the gold producer is one committed by the State itself, and is therefore irremediable excepting through the agency of the State: the other is incidental to the ordinary course of business, and remediable by the operation of the law of supply and demand.

I have long maintained that, apart from the McFadden bill, Congress should remedy this particular injustice to the gold producer. It may be advisable, in view of the necessity for maintaining the gold standard without fluctuation, to preserve unchanged the quantity of gold in standard coin, regardless of the hardship, at times of high cost, to the miner who produces the gold; but I can see no corresponding necessity for compelling him to produce, at a loss, the gold used in the arts. The proper function of the Mint is to coin into money the bullion deposited with it. It should not store gold for the benefit of the Federal Reserve Bank, nor sell it to manufacturers of jewelry. The law should specifically forbid the destruction of the money so coined. The existing law forbids its defacement or mutilation; but the Treasury construes this provision as not including total destruction.

I have heretofore pointed out that gold producers have, in some measure, the remedy in their own hands. They should arrange, in concert, to deposit bullion in the Mint, withdraw gold coin to an equivalent amount, and put it into circulation by paying it out as wages, etc. Precisely how much of a premium this would compel the manufacturers of jewelry to pay, I do not know; there would certainly be some premium, due to the cost of melting, loss in weight of coin, etc. It is possible that the fashion of using gold coin would rapidly extend, at all events throughout the Western States: in which event the jewelry trade might conceivably be forced to purchase foreign gold. The plan should, in my opinion, have been tried out long before this.

GEORGE E. COLLINS.

Denver, December 6.

ON the shores of the Dead Sea and between Jerusalem and the Nebi Musa is found a peculiar stone, commonly used in making souvenirs, states a consular report. The Bedonins have used this for several years as fuel, and it is reported that during the War it was so used by the Germans. The stone is called Dead Sea stone or 'stinkstein'. In the Yarmouk valley in northern Palestine are also found vast quantities of an oil-impregnated shale. When burned this shale leaves a fine quality of lime, which, when air-slaked, is said to be suitable for building purposes.

CONCENTRATING PLANT AND SMELTER

Ball-Milling and Flotation at Catemu, Chile—I

Milling Operations

By F. Benítez

The Catému valley, where most of the mines of the Catému company are, is in central Chile. The mines are situated advantageously, for the district is rich in agricultural produce, is well irrigated, and is, therefore, thickly populated; the climate is temperate. The company's new smelter at Chagres is on the branch line of the Central Railway of Chile; it starts at Llay-Llay, on the Valparaiso-Santiago line, and connects at Los Andes with the Transandine railway. The mines, mills, and smelter were the property of the Société des Mines de Cuivre de Catému, a French limited liability company, with a capital of five million francs; about a year ago it was sold to a Chilean syndicate. Previous to the discovery of the flotation process, several attempts had been made to concentrate the ores. Lixiviation by sulphuric acid was tried on the oxidized ore of the Verde mine, but the results were unsatisfactory, and the plant was soon dismantled. Later, a gravity-concentration mill was erected at La Poza, where the old smelter was situated, but proved a total failure. The mill was re-designed and machinery was purchased, but this was never erected, perhaps through lack of faith. The failure of the ordinary concentration mill is not surprising when the inefficiency of some machines is considered.

The copper minerals in all but one of the Catému ores are finely disseminated throughout the gangue, so that it

is necessary to grind them finer than 100-mesh to liberate the sulphides. The successful application of the flotation process to the treatment of copper ores and the satisfactory recoveries obtained on slime in the United States and by the Braden Copper Co. in Chile directed attention to the possibility of using flotation as a system of concentration for the Catému ores. Laboratory tests proved the amenability of the ores to the new process, and were satisfactory enough to justify the erection of a small plant to treat the output of the Mantes mine. Consequently, plans were prepared for a 70-ton flotation mill, utilizing in great part the old machinery and the old site. This mill was defective in many ways and should never have been considered other than as an experimental unit. But it served as a trial mill, and in addition was able to pay for itself, and even to make a profit. This was due in great part to the keenness, foresight, and energy of E. D. Pope, who designed and erected the Poza and Chagres mills and was the general milling superintendent until February 1920.

The Poza plant treated, from the time of its erection at the end of 1916 to December 1919, 55,000 tons of ore assaying 3.5% copper, of which 0.46% was oxidized. The concentrate assayed 16.3% copper, and the total recovery was 80.6%. A rough outline of the Poza flow-sheet was as follows: The ore was crushed in a 9 by 15-in. Dodge

crusher to $1\frac{1}{2}$ in. Two 26 by 12-in. rolls in series further reduced it to $\frac{1}{4}$ in., at which size it was fed to an 8 ft. by 30-in. Hardinge pebble-mill, working in closed circuit with a drag-classifier delivering an 80-mesh product. The overflow from the classifier was laundered directly to a 12-box, standard, belt-driven M. S. machine. The size of the agitating-boxes was 18 in., with 12-in. agitators. The first five boxes made a finished concentrate, and the pulp from the other seven overflowed and was returned to the head of the machine. The tailing was divided into sand and slime in a Dorr classifier. The sand went to a Wilfley table, and the slime to two standard Callow cells in series. The table made a finished concentrate, but the overflow from the Callow cells was cleaned in a smaller air-cell, which made a finished concentrate and a middling. The results obtained at the Poza plant, though not satisfactory as to recovery, were encouraging enough to justify the erection of another mill at Chagres, where

integration by rain; a plaster coating made of 1:3 mixture of cement and sand was added outside. This construction, which is used throughout central Chile, has the advantage of cheapness; moreover, Chilean masons are experienced and quick at this kind of work. It has the disadvantage, however, that frequent repairs are needed; over long periods of time it will prove to be more expensive than corrugated iron.

FLOW-SHEET. The ore is brought from Curimon to the Chagres station, a distance of 30 km., in the ordinary 20-ton trucks of the State railway. At Chagres it is shoveled from the railway car into one-ton Decauville cars and dumped into a *cancha* or concrete plat, which serves as a receiving-bin. The capacity of this plant is 400 tons. The ore is taken to the mill-bin in half-ton

SUGGESTED

the company's new smelter was being constructed, to treat the output of the Caracoles mine. This mine is not in the Catemu group, but is on one of the lower spurs of the Andes (called Rinconada de Los Andes) in the Aconcagua basin. The ore has to be brought eight kilometres by bullock-cart to the Curimon station on the Llay-Llay Andes branch railway, and another 30 km. by this railway to the mill at Chagres. Because of the heavy cost of transporting the ore to Chagres, the mill should have been built at the mine, where a favorable site was available. By so doing the company would have saved the difference in the cost of transport between ore and concentrate, respectively.

MILL-SITE. The Chagres mill was constructed on a flat site, which had the further drawback of being situated on the old bed of the Aconcagua river—an unsatisfactory foundation on which to erect heavy machinery. The building itself covers 3000 sq. ft., and is of local timber, oak and poplar having been used throughout. Oregon pine would have been preferred, but owing to the War none was available in Chile at the time. The walls of the building were built of adobe on edge, to prevent dis-

integration by rain; a plaster coating made of 1:3 mixture of cement and sand was added outside. This construction, which is used throughout central Chile, has the advantage of cheapness; moreover, Chilean masons are experienced and quick at this kind of work. It has the disadvantage, however, that frequent repairs are needed; over long periods of time it will prove to be more expensive than corrugated iron.

ears, and is weighed before dumping. A large amount of re-handling and shoveling is necessary before it reaches the concentrator bin; all this would have been avoided had the mill been erected at the mine.

Most of the machinery used in the Chagres mill was old-fashioned. The M. S. machine and the Frenier pump were new, and were the only units that never gave trouble. The altered Ferraris mill calls for special comment, for the trouble it gave, and also because the kind of support adopted is coming into favor again, in connection with some types of roller-mill. The manager did not wish to buy a new mill for the Chagres concentrator, so it was decided to make an ordinary overflow trunnion-discharge mill by bolting two Ferraris shells together, but to keep the old under-carriage. The mill would not be suspended from the trunnions, but would run, like the true Ferraris, on rollers or carrier-wheels. It was not possible to use the manganese-steel shell-liners of the original mill on account of their small length and design, so a lining made of heavy railway rails (50-lb.) was designed by Mr. Pope. The method of fixing the rails was the same as for the shell-liners of the original mill. The

Ferraris-mill heads carried a protruding rib around the periphery on which the shell-liners rested. These were held in position by the head-liners. The head-liners were fastened to the heads in the ordinary manner by means of countersunk bolts. Thus the whole of the shell-lining on the Ferraris mill was secured by means of the head-liners and the heads. In order to hold the rails in place they were sawn to the right length (59 in.), and a notch was cut in the web of each to fit exactly into the protruding rib of the head and at such a height that the base of the rail rested on the mill-shell. When all the rails were in position, the end was closed by bolting the head to the mill-shell, and a rich mixture of concrete and sand was poured in around the rails and allowed to set. The lining never gave trouble; it wore evenly and well. I have seen lately* that the same type of lining has been used by E. B. Morse with much success.

The diameter of the Ferraris shells without the lining was 5 ft. 1 in., and with the lining 4 ft. 3 in. (5 in. for each rail). The length of the two shells together was 4 ft. 10 in. inside the liners. Therefore the performance of this mill can be compared with that of a 5 by 5-ft. cylindrical mill. However, the large diameter of the feed and discharge cones (23 in.) reduced considerably the effective available volume of the mill for the load of balls, so that the mill would carry only 4200 lb. as a maximum. The original assorted load of balls was as follows:

	Total weight
132 balls 2½ in. to 3½ in., average weight 4 lb.	530 lb.
114 " 3½ " " 4½ " " " " 9.7 lb.	1110 "
160 " 4½ " " 5 " " " " 16.3 lb.	2600 "
Total weight	4240 "

As the mill had to work in closed circuit with the drag-classifier, the feed-cone was fitted with a two-way scoop-feeder of 34-in. radius, made at the company's workshops. Lack of head-room from the crusher to the centre of the mill made it necessary to feed the coarse ore into the feed-box, which was unorthodox practice. The mill ran at 28 r.p.m., and was belt-driven from a 60-r.p.m., 13-amp., 2500-volt induction motor. Although the mill was a success metallurgically, for it did the work it was designed to do (40 tons per day from 1½ in. to 80-mesh), it was a complete failure from a mechanical point of view. The rollers broke under the terrific vibration; the stoppages were frequent and lengthy, as tackles and jacks were the only means available for pulling the mill to one side in order to reach the broken roller. Because of frequent breakages it was decided to replace the hollow rollers by solid ones. As the scoop was blamed for the trouble by the mechanical section, though it was entirely innocent, a bucket-elevator was inserted between crusher and mill. The real cause of the trouble lay, however, in the unequal diameter of the steel tires, which made the mill wobble on the rollers. If the tires of the two short mills, after coupling, had been turned as a single unit it is possible that the breakage of the rollers

would have been avoided, or at least reduced considerably. The periodical turning-down of the tires and rollers would have been unavoidable, however, for they wore unequally. At the feed-end of the mill, sand from the classifier would lodge between the tire and the roller, causing them to wear more rapidly than those at the other end. On one occasion, after the mill had been in operation for four months, the three tires were measured. The one at the feed-end was found to be 7 mm. smaller than the one at the discharge end, which always remained cleaner.

The speed of the mill was reduced to 23 r.p.m. in order to minimize the vibration without unduly reducing the capacity of the mill. Minus the scoop and with the solid rollers the mill ran more smoothly than previously, but the elevator gave trouble because of the sticking together of the feed from the crusher, which was dry, with the returns from the classifier, carrying 25% moisture, in the boot of the elevator. The ore, being clayey and sticky, gradually filled the boot and buckets. To avoid this, the scoop was again fitted to the mill, but this time the coarse ore from the crusher was laundered to the centre and only the classifier return was scooped. With the dry feed, the elevator worked as well as could be expected; but I would never put an elevator in a mill; it is a source of trouble and annoyance, no matter how well designed. With solid cast-iron rollers, and with the feed going in at the centre of the scoop, the mill worked fairly well; but after it had been in operation for some time the tires and rollers wore unequally, causing the middle tire to hammer on its supporting roller; this hammering rapidly crystallized the steel of the carrying-shaft, which always broke inside and at the centre of the middle roller. Once the tires had worn unequally, shaft after shaft was broken; on one occasion both shafts snapped at the same time. The shafts always broke at the centre of the middle roller, in spite of the fact that the roller-carrying shafts were of 3½-in. diameter, of mild steel, and that both key-seats and keys were accurately cut. The keying of the rollers to the shafts had to be done carefully and the keys driven home true and hard, otherwise the rollers would loosen rapidly. The bill for direct repairs of these mills was heavy; besides, the mill was idle about one-third of the time. In view of the hopelessness of making the altered Ferraris operate satisfactorily it was decided to buy a trunnion-suspended ball-mill to replace it. I have dealt at length with a type of mill support that is today almost obsolete, not only because our experience may be of interest to others, but because I have noticed of late a tendency on the part of manufacturers to come back to it, at least in connection with rod-mills. The Marathon mill, described by M. F. C. Blickensderfer in Vol. LV of the Transactions of the A. I. M. E., has almost the same support as the Ferraris, that is, tires supported by and revolving upon rollers. The author, in his description of the mechanical defects of the original mill, mentions the roller-bearings as unsatisfactory and alludes to the excessive vibration that was caused by a lack of rigidity in the understructure.

*'Steel Rails as Ball-Mill Lining.' 'M. & S. P.', April 2, 1921.

No trouble seems to have arisen in connection with the wear of tires and rollers, but perhaps the mill was not operated long enough. The manufacturers of the Macey roller-mill seem to have effected a compromise; for whereas the feed-end of the mill is supported by a trunnion-bearing, the discharge-end is supported by a tire that revolves upon two rollers. Otherwise the mill seems to be all that can be desired from a mechanical point of view. The reason for having chosen the tire-and-roller support in preference to the bearing support for one end lies undoubtedly in the design of the discharge-end and door, where it would not have been possible to put a trunnion bearing.

The Allis-Chalmers Manufacturing Co. has gone a step further in design: its rod-mill is of a double-trunnion type, but can be supported on rollers when the discharge-end head is removed. From the point of view of rigidity, lower maintenance cost, security, and mechanical efficiency, I do not think that anybody will question the superiority of the bearing-type of support as compared with the tire-and-roller type.

DRAG-CLASSIFIER. The drag-classifier used, which was built locally, was of ordinary design, with a 35° slope and a chain-speed of 45 ft. per minute. This machine was also a continual source of trouble, expense, and annoyance. Mechanically, it was costly in upkeep, as it needed frequent renewal of links and rakes. Metallurgically, it was inefficient, as it allowed too much coarse material to overflow, and returned too much undersize to the mill. Perhaps the slope, or the speed of the chain, or both, were not right for the classification required; but in any case this type of classifier, though perhaps useful as a dewaterer or as a sand remover, lacks the flexibility of the modern mechanical classifier such as the Dorr, in which, by quick and simple means of adjustment, a wide range of products can be obtained. Even a considerable increase in the dilution of the pulp in the drag-classifier caused only a small change in the separation. The drag consumed 5 hp., as compared with the $\frac{3}{4}$ hp. necessary for a Dorr classifier of the same capacity.

Both mill and classifier having proved failures, it was decided to erect a 4½-ft. by 16-in. Hardinge ball-mill to operate in closed circuit with a 2 ft. 3 in., Model C, Dorr classifier. Owing to war conditions, it was doubtful when the machinery would arrive in Chile, so it was deemed advisable to continue working with the Ferraris, inefficient as it was, and to have the foundations ready for the new mill. Either mill could be fed from crusher and elevator. Although the 4½-ft. by 16-in. Hardinge mill was satisfactory from a mechanical point of view and always ran 100% of the time, it was unable to do the work demanded of it, which was 40 tons per day from 1½ in. to 80-mesh. The mill was loaded originally with 3500 lb. of chrome-steel balls, of which 1300 lb. was of assorted balls, ranging in size from 2 to 4 in., and 2200 lb. was of 4-in. balls weighing 9.4 lb. each. The maker's catalogue stated that the 4½-ft. mill would take 4200 lb. of balls, but 3500 lb. was all that could be fed.

As a rule I have found that ball-mill manufacturers exaggerate the load of balls that their mills will take by as much as 40%. The Hardinge mill and Dorr classifier combination was a great improvement, for both machines worked well, and delivered a uniform and steady feed to the M. S. machine.

The mill, which was run at 34 r.p.m., required 18 hp.; the motor driving it was of 30 hp. The mill ground 20 tons of Caracoles ore per day from 1½ in. to 12% on 80-mesh. Of the classifier overflow, 60% would pass a 200-mesh screen. The moisture in the mill was varied from 20% to 60%; it was found that the best results were obtained with about 30 to 35%. When the ore was soft and clayey, 35% water was desirable; when hard and compact, 30%. If the water was reduced much below 30% the mill would discharge a considerable amount of coarse ore. This was undoubtedly due to the fact that no classifying action took place in the mill when the pulp became too thick and sticky. When the proportion of water in the mill was correct for the particular ore under treatment, and when the feed did not exceed the maximum amount that the mill could efficiently grind, the large pieces of ore were retained in the cylindrical portion of the mill until ground, and the discharged product was fairly uniform in size. If the water was reduced to, say, 20%, the mill would begin to discharge ore that was considerably coarser, even if the rate of feed was not increased. By closing the jaws of the crusher to $\frac{3}{4}$ in. it was possible to grind 25 tons per day to 12% on 80-mesh.

The experiment was tried of crushing the feed for this mill in the 48-in. vertical Symons disc-crusher at the smelter. On this feed the mill worked better than on a Blake product, and a tonnage of 25 tons per day to 80-mesh could easily be maintained, even by the Chilean operators. However, the increase in capacity of the mill with the final product of the Symons crusher as compared with that of the Blake crusher was not sufficient to offset the greater cost of crushing and transport from smelter to mill, so the change was discontinued. There is no question that the Symons disc machine delivers a better product for a ball-mill than does a crusher of the Blake, Dodge, or gyratory type. Although the amount of oversize remaining on any screen, say, of 1-in. round holes, be the same for both types of machines, the oversize from the disc consists of long, flat, slaty pieces, which can be more easily crushed by a ball of a given weight than can the cubical pieces delivered by a crusher. Although admittedly a Blake crusher and a ball-mill working in closed circuit with a mechanical classifier provides a good combination for the reduction department of a small flotation mill, on account of simplicity of arrangement and low cost of installation, the ball-mill should be of sufficient diameter to crush easily large pieces of ore. The Blake crusher should be also of sufficient capacity to give a large reduction range, in order that the mill may be fed with the finest product possible. If a small-diameter mill, such as 4½ or 5 ft., is fed with coarse ore, 2-in. cubes for instance, its capacity will be

reduced greatly, even though large balls be used. This will result in low grinding efficiency. After a time only 5½-in. steel balls, weighing 26 lb. each, were fed to the Hardinge mill, but no appreciable gain in capacity was noticed, although less oversize was discharged. This seemed to prove that a greater ball load will not compensate for insufficiency in diameter. The discharge of such accidental oversize, containing pieces of ore up to 1 in., was a nuisance, for it reached the Dorr classifier; but it speaks well for the rugged construction of the classifier that no part either broke or bent. Mr. Dowsett's method of preventing the discharge of such oversize—a spray pipe with a small nozzle at the end of the mill, placed so that it discharges on the lifting side of the pulp-load and about 18 in. inside the mill—was tried, but no appreciable benefit resulted. The idea was to maintain the consistence of the pulp uniform throughout the mill by feeding the water at both ends. When all the water is added at the feed-end, the pulp at the discharge end is less wet because of an increasing rate of water absorption as the ore is ground. This defect is remedied by adding some of the water at the discharge end, whereby the classifying action of the cone can take place. As the Hardinge mill could not handle the tonnage desired, which was 50 tons per day through 100-mesh, it was decided to order a 5 by 4-ft. Allis-Chalmers granulator, which the makers guaranteed would handle the tonnage.

The preference given to a cylindrical mill calls for an explanation; at first hand it would appear that the change was due to dissatisfaction with the conical mill, but this was not so. The Hardinge mill gave every satisfaction. It always ran 100% of the time, which proves that, from a mechanical point of view, it is well-nigh perfect. It did not grind the ore because it was too small. I am sure there is no mill on the market of an equivalent size that takes the same power and on the same ore could better its performance. The Hardinge mill has the advantage of simplicity of construction and operation. This is a point in its favor not to be lightly disregarded, especially in countries where labor is unskilled. The Chilean operators learned quickly how to work it. In a small plant, where no overhead crane or other facilities are at hand, the simplicity with which a worn-out lining can be removed and a new one substituted is another advantage in favor of the conical mill. The mill-manager favored a 6-ft. by 22-in. Hardinge mill, but he was overruled, and a 5 by 4-ft. Allis-Chalmers granulator was ordered.

Pending the arrival of the Allis-Chalmers mill, and in order to run the plant nearer its full capacity, it was decided to operate the Ferraris as a primary mill and the Hardinge as a re-grinder. The original Ferraris was a short cylindrical mill. Its outside dimensions were 5 ft. diameter by 2 ft. 6 in. long. Inside the liners it was 4 ft. 2 in. by 27 in. The lining was of manganese steel, and consisted of long flat plates alternating with short thick lifting-bars. Bars and plates did not fit exactly, so that ore already ground sufficiently fine would dis-

charge through the bottom and between the liners. The ground ore and water would gravitate into the screening compartment, which was divided into a series of pockets by means of a cone projecting into the crushing-compartment and a series of radial partitions extending therefrom. The periphery of the screening-compartment was open, and was surrounded by a screen of the desired mesh. The material not fine enough to go through the screens was elevated by radial partitions; and, sliding back on the surface of the cone, was returned to the crushing compartment.* This mill was operated at 22 r.p.m. and required 20 hp. (motor input). The lifting-bars gave the balls a considerable lift, greater than in any other ball-mill I have seen, and perhaps too much. The charge consisted of forty 5½-in. balls weighing 26 lb. each, or a total weight of 1040 lb. The mill required an excessive amount of water, at least as measured by present ball-mill practice; otherwise the screens would choke badly. It produced a small amount of slime, and must be an ideal grinder for table concentration. At first, 4-mm. round-hole, punched screens were used. These did not give sufficient capacity, so that 8-mm. screens were substituted. Thus equipped the mill ground 46 tons per day from 1½ in. to 8 mm.

The ground ore from the Ferraris mill was elevated by means of a 10 by 54-in. Frøner pump into the Dorr classifier. It was remarkable that this pump, which is supposed to be a sand-pump, should have been able to handle such a coarse product. Trouble was experienced because chokage occurred at the elbow of the discharge pipe, but by increasing the amount of water this was overcome. This excess of water diluted the pulp over much; too much sand was returned from the Dorr classifier to the Hardinge mill, which choked. Consequently a 5-ft. Callow cone was installed, and the excess water was removed as overflow. The grinding arrangement described was far from ideal, but it enabled the plant to handle 40 tons per day until the Allis-Chalmers mill arrived. It was erected upon the same concrete mass as the Ferraris. It has been in operation for 15 months, and I can compare it with the others. This mill is belt-driven from a 60-hp., 14-amp., 2500-volt induction motor with tramway controller. As the speed of the motor was only 400 r.p.m., no intermediate counter-shaft was required. The driving-pulley was a Type A, friction-clutch pulley made by the same manufacturer. It gave trouble owing to heating, and on this account it was keyed directly to the driving-shaft and used as a plain pulley. Since discarding the clutch-pulley no trouble of any kind has been experienced in starting the mill. The original load consisted of 5600 lb. of forged chrome-steel balls, ranging in size from 2 in. to 4 in., the 4-in. balls greatly predominating. With this load, the driving motor takes 62 hp., and, allowing for the loss in transmission, the mill requires about 50 hp. The feeder is of the combination type, 36 inches in radius, of strong construction, and will handle balls up to 5-in. diameter. It has never choked, in spite of the large amount of sand

*From Richards' 'Ore Dressing'.

from the classifier, at least 250 tons per day. The lining is of manganese steel, and the shell-liners are of the ship-lap type.

A peculiar feature of this mill is its variable-discharge diaphragm, by means of which the discharge-level may be regulated and maintained at any point between the periphery and half-way to the centre of the mill, to suit the character of the ore and the ratio of reduction desired. The pulp is discharged through eight rectangular grates or screens, 3 in. thick. These are made of tempered, rectangular tool-steel bars that are set on edge and spaced $\frac{3}{16}$ in. on the inside and $\frac{5}{16}$ in. on the outside, that is, they are tapered to prevent choking. The grates themselves are held in position by wedge-shaped manganese-steel liners, secured by bolts. The intervening spaces between the rectangular grates is filled by triangular-shaped liners that are also held in place by bolts. Behind each grating is a pocket in the face of the diaphragm, to allow the pulp to discharge freely through the grate. The back of this depression is perforated with a number of round holes, thus allowing the pulp to discharge into the spaces between the lifter-arms. With all the holes left open the mill will discharge at the periphery, but by closing the outer holes with wooden plugs the discharge is raised accordingly. If only the two innermost holes are left open, the mill will discharge one-third from the centre, and it will then be almost as full of pulp as the ordinary type of trunnion-overflow mill.

After the mill had been in operation for some time and when its operation was thoroughly understood, tests were made to find out what was the best height of pulp. It was necessary to grind the maximum tonnage possible from $1\frac{1}{2}$ -in. feed to 1% on 100-mesh, with the mill working in closed circuit with mechanical classifier. In every instance it was found that the mill worked most efficiently and at its maximum capacity when discharging at the periphery. Our particular case was a problem of fine grinding in one stage; therefore, from theoretical considerations, it would appear that a high level of pulp should have been found more beneficial than a low one. Such was not the case; in our experience in treating four different kinds of ores in this mill the necessity never arose of having to plug up holes to raise the pulp-line. Furthermore, it was found that the regulation of the level of pulp in the mill could be accomplished far more rapidly by altering the density of the pulp. By increasing or diminishing the amount of water, the mill could be made to discharge either at the periphery (water, 35 to 45%), or even through the central pipe (water, 20 to 25%). In the latter case the mill would be full of pulp (choked) like an ordinary overflow mill. This does not mean to imply that the mill was not discharging through the grates, but that by reducing the water in the mill sufficiently the pulp could be retarded as long as desired. Soft Caracoles ore would go through the mill rapidly with 35% moisture, producing a granular product. Under these conditions the raking capacity of the Dorr classifier would be exceeded, and it would

either stop or would allow a proportion of coarse material to overflow.

Decreasing the water in the mill to about 30% would remedy this trouble, as the pulp would be retained longer in the mill, and the discharge would, therefore, contain a greater proportion of finished product (minus 100-mesh), which would overflow from the classifier at once, reducing the circulating load to a point where the classifier could handle it. On the other hand, in treating Salado ore, which is a rhyolitic lava with bornite filling the 'steam' cavities, grinding to 48-mesh is sufficient to free the mineral. Further, as the minus 200-mesh material in the tailing carried more copper than any other size, it was desirable to slime as little of the mineral as possible; consequently, the mill was operated with 40% water, which allowed a rapid change of the contents. Therefore, without the necessity of plugging any holes in the diaphragm, widely varying conditions were met by altering the amount of water. This being so, I do not see the need of encumbering the mill with a diaphragm that merely increases weight, reduces length, and is bound to make the mill more expensive. If the advantages of the grate-mill depend—as put forward by advocates—on peripheral discharges, low pulp-line, quick discharge of fine, greater efficiency of ball-load, and non-selective action between mineral and gangue, I do not see the reason for disregarding some of these advantages by artificially raising the height of the pulp. At best the Allis-Chalmers diaphragm seems to me to be a sort of compromise between the overflow mill and the grate-mill.

The capacity of this mill when working in closed circuit with a mechanical classifier was 50 tons per day from $1\frac{1}{2}$ in. to 2 to 5% on 100-mesh of Caracoles ore, and the same tonnage of Salado ore from the same size to 2% on 48-mesh, this ore being harder to grind than the Caracoles ore. The same reduction in capacity as with the other mill was noticed when fed with coarser ore. With the Blake closed only to $2\frac{1}{2}$ in., the tonnage dropped to 42 per day. Therefore the contention of ball-mill manufacturers that the capacity of a mill is only increased to a small amount by feeding it with a smaller feed seems to hold true only in the case of large-diameter such as 8-ft. mills. With the smaller mills the capacity can be increased appreciably, as much as by 25%, by giving the mill a feed such as the largest balls can easily crush. It was found unnecessary to charge the mill with more than 5500 lb. of balls, instead of the 9000 lb. mentioned in the catalogue; the mill worked more efficiently with the smaller load, which was 8 in. below the axis. The experiment was tried of loading the mill to the axis, and it was found that its capacity decreased and the power-consumption increased. It was impossible to deliver the feed into the mill; the ore stayed in the drum of the scoop. The speed of the mill was 25 r.p.m., the power not being sufficient to run at 28. Under the best conditions, the mill crushed as much as 62 tons of Salado ore per day. The consumption of balls was 1.43 lb., and that of liners 0.654 lb., per ton of ore ground.

Life, and Cost per Ton, of Liners for Allis-Chalmers Granulator

Section	Life in tons	Cost, cents per ton (U. S. Cy.)
Throat-liners	6,000	1.00
Diaphragm-wedges	11,820	1.37
End-liners	11,820	1.51
Grates	13,000	1.45
Diaphragm-liners	13,000	1.24
Shell-liners (estimated).....	17,000	9.35
Total		15.92

The through-bolts holding the liners in the Allis-Chalmers mill seem to me to be faulty in design; they do not allow the liners to be worn completely, and about one-third to one-quarter of the weight of these expensive manganese- or chrome-steel liners has to be thrown away. (See Fig. 3. The unshaded part is wasted.) A set of throat-liners was weighed when new and when worn out. The amount of the liner that could be used was 61.2% only. With the type of bolt supplied, and as soon as the head wears, the bolts will no longer hold, and the mill will leak badly through the bolt-holes. It is useless to try to tighten the bolts, for, as they lack the square head, they will either turn with the nut or come through the lining altogether. Therefore the semi-worn liner must be replaced, or new bolts must be put in. As the counter-sunk section of the liner has been worn through, the whole of the square heads of the new bolts protrude inside the mill; here they are knocked about by the balls, and loosen rapidly. An improved type of through-bolt, it seems to me, would be one in the form of a truncated square pyramid as shown in Fig. 4. This type of bolt-head would enable almost all the liners to be worn. The matter is worthy of investigation by mill manufacturers, as ball-mill men cannot but sigh ruefully on seeing so much money go to the waste-heap in times such as these, when a matter of a few cents per ton may make all the difference between profit and loss. A cent saved is a cent earned.

On comparing the actual discharge-areas, one cannot but be struck by the much greater discharge area of the Marey mill as compared with that of the Allis-Chalmers mill. In the Marey, the discharge-end is entirely in the form of grates, whereas in the Allis-Chalmers mill there are 16 blind-liners that reduce the area considerably. The actual area of discharge in the Allis-Chalmers 5 by 4-ft. granulator was found to be only 7.7% of the total. I do not know what the actual open space of the Marey-mill grate is, but it is certainly much greater. The 'chord' arrangement of the Marey grizzly-bars that make up the eight grate-sections is also superior, in my opinion, to the radial spacing of the grates in the Allis-Chalmers mill; in the former the grate will present a continuous opening to the discharging pulp. Except for the slight defects mentioned, the 5 by 4-ft. Allis-Chalmers granulator gave entire satisfaction, and it was only after it began operating that it was possible to run the mill efficiently, and to give the necessary time and attention to the flotation of the ore.

(To be Concluded)

Talc

*Talc is a hydrated silicate of magnesium. It has a specific gravity about 2.7, is soft, and has a characteristic soapy feel. Ordinary talc is foliated, but the laminae, though flexible, are not elastic. In color it varies from white, gray-green, apple-green, to dark green. It is not acted upon by ordinary acids and is a poor conductor of heat and electricity. When heated it loses a small amount of water, hardens, and can be polished. The compact fine grained variety of talc is known as steatite or soapstone. It is usually gray in color and has a crystalline structure. A comparatively impure variety is known as potstone. Much of the talc or steatite of commerce is the mineral pyrophyllite, a hydrated silicate of aluminum; it is somewhat harder than talc, but otherwise closely similar in its physical characteristics. The name agalmatolite is applied loosely to both steatite and pyrophyllite.

Talc is subjected to careful sorting at the mine. Pieces that by their texture and color are deemed suitable for cutting are set aside for subsequent sawing into slabs, from which are manufactured lava-tip gas burners, and tailors' crayons and pencils. A large amount is used in the form of sticks and pencils for marking purposes in iron and steel works. The residue is usually sorted and graded according to the color of the material, but some prefer to sort to one uniform standard, discarding all varieties of color other than that selected. Dressing operations consist of crushing, grinding, and grading. Simple screening is the method generally adopted for grading. Latterly, considerable attention has been given to pneumatic separation, and many separators have been devised to work by this method. Probably 90% of the talc mined is ground to flour and used in the manufacture of paper, molded rubber goods, and foundry facings. Only the highest grades of white talc can be used for toilet preparations such as talcum powder. Very high-grade talc powder is used in medicine. Other important uses for ground talc of good grade are in the manufacture of French chalk and soap, and for lubricating purposes. It is also used as a filler in the manufacture of certain classes of linen and cotton fabrics. Talc has a considerable power of absorption and this property is utilized in bleaching cotton goods and for cleaning silk and other cloths. Much powdered talc is used in the manufacture of waterproof paints, and the fibrous variety is used by manufacturers of gypsum wall plasters. Low-grade ground talc finds a limited application as a polish for glass and leather. Commercial ground talc must be free from impurity. The objectionable minerals are quartz, unaltered amphibole, pyroxene, iron ore, iron pyrite, calcite, and dolomite.

The use of talc, particularly the fibrous variety, as a filler in the manufacture of paper of nearly every grade, is rapidly extending. Soapstone is used for lining stoves and furnaces. Steatite, which is a bad conductor of electricity, is suitable for paneling switchboards.

*Abstracted from a bulletin issued by the Imperial Mineral Resources Bureau, London.

A Christmas Message

By Herbert Hoover, Secretary of Commerce

The economic recovery of Europe is necessarily slow and difficult. It contains great dangers, but it is not at all as gloomy as some statements would make it appear.

Since the Armistice, the combatant states (except Russia) show steady gains in social and political stability; they show great progress in recovery of agriculture, industry, foreign trade, and communications. The one field of continual degeneration is that of governmental finance—that is, the unbalanced budgets, the consequent currency inflation of certain countries with its strain of credit destruction.

The most eminent and most dangerous of these unbalanced inflation situations is that in Germany. Her case depends upon the method and volume of reparation payments. As the United States does not participate either in its control or its receipts we have no voice or right to interfere. In any event this is particularly a European matter and must be adjusted by the parties at interest. It is earnestly to be hoped that the present negotiations upon reparations may succeed in finding a sound basis that will ensure permanent economic and political stability to Germany, and certainty of regular payment to the Allies. With this effected, the way is open for constructive consideration of the situations in other states.

The American people have never been and will not be remiss in participation in these further measures, but our people cannot successfully enter until those who have control of reparations have settled this major issue upon so sound an economic basis that we can look upon the future of Europe with confidence.

Outside of government finance of a limited number of states, the outlook is very encouraging. Any general survey of the social situation in Europe will show that danger of bolshevism is passed, partly through improved standards of life and partly through the salutary lesson of Russia. Democratic institutions are gaining strength among the 150,000,000 people formerly supporting autocracies. In Russia itself extreme communism is slowly boiling to death in a cauldron of starvation and its leaders freely acknowledge failure.

In international political relations, aside from conflict in Turkey, war has ceased and treaties of peace are effective throughout the world. Warring states have settled for a time their major territorial issues, and while there are remote forces of instability, the new boundary alignment is winning acceptance, and agencies for allaying international friction are proving themselves steadily more effective. There are bright prospects of limitation in naval armament. Agreed limitations in land armament are not very hopeful, but the economic pressure of taxes and unbalanced budgets is slowly disarming the countries of Europe, and it will disarm more of them yet. The number of men under arms has decreased by fully a million in 12 months.

In the field of economic life, the progress of agricultural and industrial production since the War is very

marked. Famine has disappeared from Europe save in Russia. Except in countries where credit machinery is checked by danger of fiscal bankruptcy, as is the case of Austria, food, fuel, and clothing supplies are sufficient, albeit, with a low standard of living in some places; but even in these countries the standards are much higher than the low point after the Armistice. Populations have fairly settled to work and industrial efficiency and productivity are being steadily restored.

Private credit institutions of the world are demonstrating their ability to handle the international trade and credits, except for those regions excessively disabled by the currency demoralization.

Transportation and communication have been reconstructed. There are some useless hindrances to freedom of healing processes of commerce through artificial barriers between the new nations, but by and large the processes of healing are going on.

ACCORDING to estimates compiled by the U. S. Geological Survey in 1908 and reviewed by the Department of Agriculture in 1916, the water-power resources of the State of Washington amount to 125 hp. per square mile, or a total of over 8,500,000 hp., states a Washington Geological Survey bulletin. This gives Washington first place in water-power resources in the United States. Oregon ranks second with 68.4 hp. per square mile, and Idaho third with 60.4 hp. per square mile. The present water-power development of the State totals 408,987 hp., which is only a small fraction of the available resources. The mines are situated in the mountainous areas in the northern part of the State, so power problems for the most part are reasonably simple. Several of the companies are so situated that they can take advantage of local power resources and thus furnish the mine and mill with water-power at a low cost. The Sunset copper mine at Index and the Boundary Red Mountain mine of the Mt. Baker district form typical examples of such an installation. The majority of the mining districts are served with electric power generated by nearby power-plants. In the Oroville-Nighthawk district, the Okanogan Valley Power & Light Co. is increasing the capacity of its plant to 2500 hp. and expects to sell power on mining contracts at \$50 per horse-power-year. The Metaline mining district is well supplied with power from the large installation of the Inland Portland Cement Co. In Stevens county the magnesite and metal-mining industries are supplied with power from the Meyers Falls plant of the Stevens County Power & Light Co., and from the Long Lake plant of the Washington Water Power Co., which has completed a 40-mile pole line into the Chewelah district during 1920. The Northport smelter receives power from Bonnington Falls, British Columbia.

OF the 9054 bona fide resident students enrolled in the University of Illinois, 1892 undergraduates have registered in the college of engineering. Mechanical and electrical engineering each attract 420. Only 86 are studying mining.

Historical Sketch of Ore Treatment in Colorado

By Horace F. Lunt

INTRODUCTION. The first mining in Colorado, as in other Western States, consisted in working the gold placers. These were first worked by hand with pan, cradle, and small sluices. The gold veins, which were the sources of the placer gold, were soon located and silver deposits were discovered not long afterward. At first the precious metals were the only ones considered; copper and lead were regarded merely as necessary by-products to provide the means for the recovery of the gold and silver; zinc was highly detrimental, and, if the ore contained more than a small percentage, it was left in the ground or thrown over the dump. Rich ores were plentiful, skilled metallurgists were few, costs were excessive, much high-grade ore and most smelter products were shipped abroad for refining. Ores that were not amenable to the simple processes in vogue were passed by until a later day. Crude and simple smelting and milling methods were adapted or evolved, and have been gradually improved as the necessity for treating lower-grade and more complex ores has arisen and technical knowledge has increased.

The high cost of smelting in the early days encouraged the development of concentration and stimulated the milling of low-grade ores by various reduction processes. Special problems connected with the reduction of particular ores were met and solved by methods and devices adapted to the needs of the moment. Many of the Colorado metallurgical inventions were of transient value, or of use only under local conditions; others have proved of general application and of world-wide significance.

The first smelters were placed close to the mines. As railroads were built, the better transportation facilities made it practicable to concentrate the smelting industry at central points, such as Denver, Durango, and Pueblo, where ores from different districts could be obtained and more advantageous smelting mixtures used. The mining-camp smelters were abandoned, one after the other, until only the one at Leadville, which happens to be centrally situated, remains.

As time went on, the base metals became more and more important, until, in 1918, the value of the zinc produced in the State exceeded that of silver. Ores of rare metals, such as tungsten, vanadium, uranium, radium, and molybdenum, utterly unheard of by the pioneers, were discovered and came to have a commercial value. At first they were shipped abroad, but methods for their reduction were worked out and plants for treating them erected in the State.

SMELTING. The first smelter in Colorado was built at Nevadaville, in Gilpin county, by Caleb S. Burdsall in 1862. It burned down before it had really started to operate.¹ Another small plant was erected at the same

place in 1866, but met with no success. The first successful smelter was built at Blackhawk, in the same county, and started operations in January 1868.² At this time the gold mines, which had been discovered about ten years before, had been worked down below the easily treated outcrops, and the simple amalgamation methods of the pioneer millmen could no longer make a satisfactory saving. Various quack processes were tried without avail, and the miners were beginning to abandon their claims in the belief that they were of no further value.³ Nathaniel P. Hill, who had been a professor of chemistry in Brown university, visited Gilpin county in 1866 and was convinced that the ore could be smelted. He went back to Boston and organized the Boston & Colorado Smelting Co. to build the plant above-mentioned. Herman Beeger, who has been called the father of smelting in the West, was the metallurgist in charge. It consisted of two small reverberatory furnaces, one of which was used for calcining and the other for smelting the calcined ore to a copper matte containing the gold and silver.⁴ This matte was shipped to Swansea, Wales, for refining.⁵ Later on it was treated in Boston. In 1873 Richard Pearce, who had become associated with Hill in the management of the smelter, invented a process for refining the product, which made it unnecessary to ship anything but bullion. The plant was successful from the start; it was enlarged, and the company built a branch smelter at Alma in 1873. In 1878 the business was moved to Argo, near Denver, where it was continued until 1910, when the dwindling supply of copper ores and the competition of the lead smelters caused it to be shut-down. Other copper smelters had never had any permanent success and had ceased operations previously.

The most noteworthy detail of the operations at the Boston & Colorado smelter was the Pearce process, for many years kept secret, of extracting gold from copper bottoms. In brief, this depended on the fact that when the copper, containing gold, was heated with pyrite, under proper conditions, one atom of the sulphur combined with the copper, forming a matte, and leaving the gold in metallic form.⁶

During the 'seventies smelters were built and operated with varying success in many different parts of the State. Golden became a prominent smelting centre.⁷ The first smelter, subsequently known as the Golden Smelting Co. works, was erected in 1872, but was not immediately successful. The French smelting works was built in 1878 and the Valley smelting works in 1879. The Golden Malachite Co. built a plant in 1878 at which, for a time, acid was manufactured from Gilpin county ores.

A smelter was built by the Boston Mining Co. at St. John, near Montezuma, in 1870, in which a lead silicate was made from the rich silver-lead ores of the district.⁸ This was re-treated at Empire in a little plant that was erected by John Cullom. Cullom's plant was a failure until H. A. Vezin took charge of it in 1872. Richard Pearce's first experience in Colorado was at Empire. His lack of success there was soon lost sight of in his brilliant achievement after he became associated with the Boston & Colorado company at Blackhawk. Anton Eilers, afterward prominently identified with smelting at Leadville and later a director of the American Smelting & Refining Co., was in charge at St. John in 1875. He was succeeded by Franz Fohr, who also became prominent at Leadville.

In the early 'seventies a negro named Bowman, who had learned smelting in Mexico, operated a small Scotch hearth near Georgetown. He reduced rich galena with charcoal and expelled the resulting lead in the same furnace. Air pressure was obtained from a huge bellows actuated at first by man-power and later by a water-wheel.⁹

The first smelter at Silverton was built in 1874 by Judge Green, of Cedar Rapids, Iowa. The furnace was built of sandstone with no lining. The machinery for the plant was packed in from Colorado Springs, 300 miles away. The first water-jacket in the State was used at this plant in 1876. The year before John A. Porter had introduced the siphon-tap, but one of these had previously been used at the Swansea plant near Denver.

Among the other early smelters in the San Juan country was the Grand View at Rico, built in 1879, with which F. M. Endlich, Hofman, and Arnold were associated. The San Juan Smelting & Reduction Co. built the first smelter at Durango in 1880. Ore from the first mines in San Miguel county was packed to Silverton or Rico, for the most part, but there was a smelter at Ames in the early 'eighties.

A smelter was built at Dudley, near Alma, in Park county, in 1872, at which E. D. Peters obtained some of the experience that made him one of the leading copper metallurgists of the country. The Gooding smelter at Lincoln, in Summit county, was built in 1878, and a lead smelter at Breckenridge in 1880. The Pittsburg smelter at Kokomo and a smelter at Red Cliff were built in 1879. Riggins and Chapman, two successful lead-smelter-men

from Joplin, Missouri, in 1876, brought machinery for a plant at Alpine, on Chalk creek above Buena Vista, to treat the ore from the Mary Murphy mine. Mather and Geist started the first smelter at Pueblo in 1874.

The first two smelters at Leadville were built near Malta, in 1875 and 1876, to treat rich galena ores from the vicinity of Homestake Peak on the other side of the Continental divide.¹⁰ This was before the discovery of the lead-carbonate ores, rich in silver, that made Leadville famous a year or two later. Neither of these plants was operated long. In 1878 and 1879, after the silver discoveries, lead smelting began in earnest and 14 other smelters were built in and around Leadville. Of these, the Harrison reduction works and the Grant smelter, both opened in 1878, were, in the early days, the largest. The Billings & Eilers smelter, between Leadville and Malta, was started the following year and developed later into the Arkansas Valley plant of the American Smelting & Refining Company.

A. R. Meyer, who was in Colorado as ore-buyer for the St. Louis Smelting & Refining Co., shipped over 200 tons of Leadville ore to St. Louis. It had to be hauled in wagons to Colorado Springs, then the nearest railroad point. The ore ran 7 oz. silver per ton and 60% lead. Meyer's company built the Harrison reduction works in consequence of this test. The Grant smelter was built by James B. Grant, who subsequently became Governor of the State. The first use of cloth bags for catching smelter-fume was at this plant, where it was known as the Bartlett dust-catcher. The Grant smelter at Leadville was burned down, and, in 1882, the Grant smelter at Denver was built by its owners.

Guyard gives complete data regarding the operation of the seven Leadville smelters that were running in 1880. The fuel used was a mixture of charcoal, which was burned in the vicinity and cost \$18.50 per ton, and coke, which was obtained from Como or El Moro at a cost of \$25 or \$30 per ton. The proportion of charcoal to coke varied at the different plants from 0.4:1 to 2.4:1. The fluxes were dolomite and hematite from local sources. In the average charge 12.5 parts of dolomite, 6.51 parts of hematite, and 31.99 parts of fuel were used to 100 parts of ore; 19.94 parts of bullion, assaying 250 to 450 oz. silver per ton, were extracted from 100 parts of ore charged. The saving of silver was 96.5% and of lead 88%.

The Globe smelter was built at Denver in 1886, and the Philadelphia at Pueblo in 1888. The Ohio & Colorado smelter at Salida was built in 1900. The American Smelting & Refining Co. was formed in 1889 and included two smelters at Pueblo, two at Denver, one at Durango, and one at Leadville.¹¹ The only lead smelters now operating in the State are controlled by this company; they are the Durango and Arkansas Valley plants.

The first zinc smelter in Colorado was built by F. L. Bartlett at Canon City in 1890. The process used was de-

⁷Fossett, F., Colorado, p. 234, 1889.

vised to utilize the zinc and lead as well as the gold, silver, and copper. The ore was crushed and treated in a 'blowing-up' furnace with fine coal, whereby the lead and most of the zinc and sulphur were driven off, whereas the gold, silver, and copper were left in a matte. This matte was treated with suitable ores and fluxes in an inclined low blast-furnace and the zinc driven off as fume, leaving a high-grade matte. The fume from both furnaces was caught in bags, refined to remove impurities, and sold as white paint pigment.¹²

Subsequently zinc smelters were built at Florence and Pueblo, and zinc-oxide plants at Canon City and Leadville.

MILLING. The first mills in Colorado were erected in Gilpin county as soon as the soft outcrops were mined out and the need for crushing the ore arose. Various crude devices were constructed. The first arrastra was built in July 1859. A home-made stamp-mill with six wooden stamps shod with iron was built in the same summer. Later in the year the first imported plant, a little three-stamp mill, was erected. Other stamp-mills followed until there were 60 of them in operation by the middle of the following year. The extraction from the highly oxidized surface ores was about 75% of the gold. When the sulphides were reached, this fell to 30%.¹³ As a result, production rapidly fell off until the establishment of the Blackhawk smelter created a market for the ore.

The absence of railroad transportation and the distance that the product had to be shipped made the smelting charges very high at this period. This induced efforts to treat the lower grades of ore that could not be profitably smelted. These efforts resulted in the development of the Gilpin county stamp-mill practice, by which a large part of the gold was amalgamated and, later on, part of the valuable sulphides concentrated and smelted. In California, where stamp-mills were first extensively used in this country, the gold was easily amalgamated and the stamps were used simply to crush the ore so that the gold could be caught on the amalgamated table over which it flowed after leaving the mortar. The gold in the Gilpin county ores was not so easily saved; it had to be brought into more intimate contact with the mercury. This was accomplished by making the stamp-mill mortars deeper and larger, with finer screens over the openings; the stamps were lighter and dropped fewer times per minute. The mortars were thereby made amalgamators as well as crushers; the ore was kept in them and churned around with the mercury for a considerable length of time before it could get out. The gold that could not be thus amalgamated remained in the iron and copper sulphides which were recovered, in part, on concentrating tables.¹⁴

A distinctive form of concentrator, known as the Gilpin county bumping table, was developed. This consisted of

a table with a sloping metal surface about 7 ft. long and 18 in. wide over which the pulp flowed. A cam forced the table toward the lower end against a spring, 120 to 180 times per minute, and then released it so that the spring could force it back suddenly against a block at the upper end. This agitation caused the heavier particles of ore to settle to the bottom and be carried up and off the upper end of the table, while the water washed the lighter particles, the gangue, off the lower end.¹⁵

Gilpin county mills never saved a high percentage of the gold content of the ore. Many devices for recovering the gold in the tailing were invented and tried without success. The local practice, as described above, is a thing of the past. In the few mills that are still running, amalgamation has been discarded in most cases and modern methods of concentration are used.

The free-gold ores of Summit and Park counties, and other parts of the State where gold was discovered prior to 1890, were easier to treat than those of Gilpin county. At first, satisfactory results were obtained by stamp-milling and amalgamation. The practice of concentrating the tailing to save part of the valuable contents of the ore that was not amenable to amalgamation was soon generally adopted and became standard practice. After the discovery of the cyanide process many mills, especially in the San Juan country, were equipped to cyanide the tailing. Many dumps, where the comparatively high-grade tailings from early operations had been saved, were cyanided successfully. More recently, the flotation process has so improved the results that can be obtained, in most cases, by concentration alone that both amalgamation and cyanidation have been discarded in its favor.

The discovery, in 1891, of the telluride ores of gold at Cripple Creek, introduced entirely new metallurgical problems. Stamp-milling and amalgamation was tried first on the ores that were not rich enough to ship to the smelters at Denver and Pueblo. Ten mills, with an aggregate of 270 stamps, were built during 1892 and 1893, but, even with the addition of percussive tables and blankets, the saving was bad. The free gold would not amalgamate satisfactorily, owing to a tarnish supposed to be tellurite of iron. As depth was attained and unoxidized ore appeared, the extraction became worse and the method was abandoned.¹⁶

The first chlorination plant was built by Edward Holden in 1893, but the first well-designed mill to use this process was not completed until January 1895. It was situated at Gillett. Experiments were being made contemporaneously with cyanidation, and there was great rivalry between the advocates of the two processes. Until about 1910, chlorination was the more successful; then the improvements in cyanidation gave the latter process the advantage.

The barrel-chlorination process, as used in the various mills treating Cripple Creek ore, consisted in crushing dry to about 20-mesh, roasting in mechanical roasters to about 1600 F., and treating with electrically generated chlorine in barrels. The tailings from the chlorination barrels were treated on Wilfley tables, the concentrate, representing about 0.04 of the pulp, being sent to the smelters. The solution, filtered from the pulp in the barrels, went to vats in which the gold was precipitated by hydrogen sulphide.¹⁷

The chlorination mills in the district and at Florence were closed one after the other, and the reduction of the Cripple Creek ores became centred in three mills at Colorado Springs. The United States Reduction & Refining Co. had two plants there, namely, the Philadelphia, built in 1896 and closed in 1904, and the Standard, built in 1901 and closed in 1910. The rotary-scoop feeder, now almost universally employed on tube and ball-mills, was invented and first used at the Standard mill. The Telluride mill was built as a bromination plant in 1899; it was changed to chlorination in 1904, and closed in 1906. In 1908 it was purchased by the Golden Cycle company and re-opened as a cyanide mill. It is the only plant at Colorado Springs still in operation. The Portland Gold Mining Co. built a chlorination plant at Colorado Springs in 1902; it was changed to cyanidation in 1912 and closed in 1918.

The Portland company introduced fine grinding in cyanide solution, without roasting; agitation; and zinc-dust precipitation in its Victor mill, built at the mine in 1910. The Independence mill of the same company, also situated near the mine, embodying many improvements, was opened in 1917 and is still in successful operation. The Victor mill was closed in 1918. Several innovations have been worked out at these mills, the most important of which is the Crowe vacuum-precipitation process, which has been adopted in many other cyanide plants.¹⁸

Silver ores, which were discovered in the 'sixties in Clear Creek, Boulder, and Summit counties, were by no means as easily reduced as the gold ores. Early attempts at lead-smelting were not successful and soon gave place to reduction mills in which the silver was recovered, after the ore had been given a chloridizing roast, by leaching in a sodium hyposulphite solution or by pan amalgamation.

These plants treated second-class ores, that is, those carrying less than 200 oz. silver and not much lead. The remaining ores were shipped to smelters, either in Colorado or in Germany, England, or the East.¹⁹

The success of lead smelting, following the development of the Leadville lead-silver ores, caused the abandonment of these mills, as they saved none of the lead and a smaller percentage of the silver, with a greater operating cost, than the smelters. While the higher-grade ores could be shipped direct to the smelters, the necessity for concen-

tration soon became apparent, and mills for this purpose were erected.

During the early 'seventies, there were several chloridizing mills in successful operation in Clear Creek and Boulder counties, and the process was improved in many ways. In the Stewart reduction works at Georgetown, D. W. Brunton, who was chemist and later superintendent, in 1875, substituted calcium hyposulphite, made from the waste gases from the roasters, for sodium hyposulphite, which was then imported from Germany at a great expense. In 1876, while treating the roasted ore with sodium hyposulphite and sodium chloride, Mr. Brunton discovered that the recovery of silver was improved when there was zinc in the ore. A few experiments showed that the zinc chloride was an effective solvent of silver. The ore was roasted so as to produce a maximum of zinc chloride while chloridizing the silver, utilizing the zinc chloride as a solvent and recovering the silver by precipitating it in metallic form on copper plates. This was undoubtedly the first commercial use of zinc in Colorado, but as the zinc could not be sold, it was run to waste after performing its function as a solvent.²⁰

The oxidized silver ores of Custer county were amenable to pan amalgamation without preliminary roasting and were so treated at Rosita and Silver Cliff.²¹

Most of the surface ores of Leadville and other places that subsequently became zinc producers contained very little zinc. As depth was attained and zincy ores were encountered, efforts were made to get rid of the zinc minerals and make a clean lead concentrate that would not be penalized by the smelters. This resulted in many improvements in ore dressing. In 1885, while manager of the Colonel Sellers mine at Leadville, D. W. Brunton erected what was probably the first plant to separate galena and blende. The latter had no commercial value but, with unusual forethought, was stored in large log cribs and sold many years later. The success of the Colonel Sellers plant instigated Meyer Guggenheim, who owned the adjoining A. Y. & Minnie mine, to engage Mr. Brunton to erect a similar plant on that property.

The Wilfley table was invented by Arthur R. Wilfley, and first used by him in a mill at Kokomo, in 1896, where he was trying to effect the separation into marketable products of one of the complex sulphide ores for which that district is noted. F. L. Bartlett at Canon City, S. I. Hallett at Aspen, and probably others, were working contemporaneously and independently along similar lines, but their tables were not as successful as the Wilfley. The Wilfley table has revolutionized ore dressing and was the forerunner of all modern shaking tables with longitudinal riffles.²² It is unquestionably the most important invention ever made in Colorado in connection with the treatment of ores.

LONE RANCH, CURRY COUNTY, OREGON. OLD BORATE DEPOSITS SHOW AS WHITE SCARS IN THE FOREGROUND

Priceite, the Borate Mineral in Curry County, Oregon

By Hoyt Stoddard Gale

PRICEITE, a hydrous calcium borate, has been reported from only one locality in the United States—on the Lone ranch, in Curry county, Oregon. Specimens brought from this locality were presented to the California Academy of Science in 1872; and, after study had proved its identity as a new mineral, it was named priceite, in honor of Thomas Price, a well-known metallurgist of San Francisco.

Priceite is represented by the formula $5\text{CaO} \cdot 6\text{B}_2\text{O}_3 \cdot 9\text{H}_2\text{O}$, thus having the following theoretical composition:

Boron trioxide, B_2O_3	48.7
Lime, CaO	32.5
Water, H_2O	18.8
	<hr/>
	100.0

The mineral from Oregon is generally described as friable, chalky, and very soft, and as occurring in roundish lumps that are remarkably homogeneous and of a pure milky-white color; it is said that it is firm and compact when first taken from the ground, but that it soon softens on exposure to the air. The mineral and its deposit have been described in the literature as follows:

Chase, A. W., 'On the Oregon Borate of Lime', *Am. Jour. Sci.*, 3rd ser., Vol. 5, pp. 287-290, 1873.
Silliman, B., 'Mineralogical Notes on Utah, California, and Nevada, with a Description of Priceite, a New Borate of Lime', *Am. Jour. Sci.*, 3rd ser., Vol. 6, pp. 128-133, 1873.
Whitfield, J. E., 'Analyses of Natural Borates and Boro-silicates', *U. S. G. S. Bull.* 55, pp. 56-59, 1889.
Larsen, E. S., 'Proof that Priceite is a Distinct Mineral Species', *Amer. Mineralogist*, Vol. 2, pp. 1-3, Jan. 1917.

Priceite is so fine-grained that only under the microscope is it seen to be a completely crystalline mineral

(crypto-crystalline), an aggregation of crystals of microscopic fineness. The crystals are minute rhombic plates of the triclinic system; in this feature priceite is distinct from colemanite, which it closely resembles in composition, as colemanite is monoclinic. Silliman named the mineral priceite in his paper published in 1873, and Vom Rath gave the name pandermite to an identical mineral from Asia Minor in a paper published in 1877. The identity of priceite and pandermite is proved by the optical evidence, as has been demonstrated by Larsen in the paper cited. The mineral from Asia Minor is one of the important commercial sources of borax, and is commonly referred to in the trade as boracite, a usage which is totally unwarranted, for boracite is an accepted name for an entirely distinct mineral. Priceite somewhat resembles the weather-softened boro-silicate mineral 'howlite', found in the Calico borate district of California, and elsewhere; the term 'pandermite' has long been in local use in California to designate howlite, a usage that is, of course, incorrect. Thus much that is called pandermite is neither pandermite nor priceite, and by right of priority the term priceite should be applied to the original pandermite.

GEOLOGIC RELATIONS. The deposit of priceite in Curry county, Oregon, lies in the margin of one of the great areas of serpentine that are extensively distributed in this part of the country. The mineral was first exposed in the caved bluff overhanging Cresswell creek, so that its discovery may be considered accidental, because normally it is unlikely to crop out at the surface or to remain long exposed to the weather. The exposures at present are obscured by the soft and sliding ground that

is characteristic of broken serpentine rock. This makes mining difficult.

The sea-coast at this place shows the usual upper benches that are supposed to represent former beaches, now raised above water-level, such as are common along the Pacific coast of North and South America. The topography of the country is rugged, and the surface is intricately divided by streams. The shore is generally precipitous, with broad areas of jutting rocky headlands and intervening stretches of sandy beach. The rainfall has averaged about 80 inches per annum, and for much of the time the coast is bathed in fog. As a consequence, the ground must usually be thoroughly water-soaked, and it would not be natural to look for deposits of water-soluble minerals or readily disintegrated materials within easy reach of the surficial water. The most significant feature of the topography, in relation to the priceite deposit, is that the whole coastal slope about the deposit is a jumble of slides or slumps. This condition is shown by the general aspect of the surface; and the surface evidence is corroborated by statements of the miners who worked on the deposit underground. Slumping is a common feature in broken serpentinous rock, which in the wet disintegrates to a tale-like slippery soil, that in fact is made up of tale or related magnesian compounds. Materials that are formed in this way from the alteration of basic igneous rocks are called soapstone or steatite because of their resemblance to soap.

The occurrence of a calcium borate in serpentine is apparently unique, and so this deposit is distinctly different in mode of occurrence from the colemanite deposits of California and Nevada. There is little correspondence between the geologic relations of the Oregon priceite and those of the so-called pandermite found in Asia Minor, for the latter is described as occurring in the form of nodules embedded within a sedimentary deposit of gypsum. However, the mineral in both places may be considered to be a deposit from springs or groundwater, and to that extent of the same origin in spite of the fact that the surrounding rock is different.

Little can be ascertained as to the manner in which priceite occurs by examination of the surface, or without fresh excavations; so that we are fortunate in having several lucid and satisfactory accounts and descriptions of the mineral by those who were present at the time mining was in progress. For a particularly clear and interesting account I am indebted to Winfield Duley, who was one of the workers on the deposit in the early 'nineties. The several accounts agree on essential details. The priceite as found in place occurred principally in roundish boulder-like masses of various sizes, ranging from minute grains to a maximum recorded lump that weighed 46 tons. Each lump was perfectly homogeneous, without a perceptible particle of grit or foreign matter. The mineral was compact and firm when first taken out, but rapidly softened on exposure to the weather; hence it has always been described as soft, powdery, and incoherent. It was invariably pure milk-white in color, and resembled chalk.

The lumps of priceite were scattered in a black clay matrix, many of them in continuous lines or a system of intersecting lines. The miners dug under each lump until it dropped away from its clay matrix, leaving a cavity with dense polished black inner surface. The clay immediately around a priceite lump was so much denser than that of the deposit generally that the miner could tell by the feeling of his pick when he was approaching one of the lumps. Mr. Duley is certain that the priceite boulders have formed in place, partly because of the way the clay is compacted about the lumps, as if it had been squeezed aside. Besides, he says, each lump of priceite has a feeder in the form of a trickle of water in the back of the cavity or socket. Some of the lumps found in continuous rows stood upright like a set of horse's teeth of immense size. The lumps separated clean from the clay matrix and were easy to mine; though fairly hard when taken out, they readily broke when struck with the point of a pick.

Lieutenant Chase, in the paper cited above, gives a similar description derived from experience in the earlier mining that was done on the deposit about 1871 or 1872, when the mineral was supposed to be valuable chiefly for use as polishing powder. He says: "In cutting away the bank above the spot where the first outcrop appeared, several layers or strata were met with, of varying thickness. The first in order was a soft green clay or decomposed tale, with streaks and globules of a white waxy substance, itself another form of steatite. The second, a layer of black slate or rock broken into a thousand fragments and resembling coal. Then a layer of slate seamed with white veins and masses of decomposed tale. These layers did not contain any traces of boric acid. Then came a layer of white and hard borate, filling the seams and cavities of the slate, and pressing down on a layer beneath, which was a tough blue steatite with green and white veins, and of the consistence of clay. Wherever a hollow had been formed in the blue steatite, the hard borate pressed down into it and formed a hemisphere, the upper parts being mixed with slate, the lower pure. In the blue steatite, and a few inches below the slates, the main bed or flow was found. Here the borate was in the form of boulders or rounded masses, completely embedded in the steatite, and in shape not unlike a pumpkin or squash, the sides being corrugated and having little depressions in the top surface. These boulders formed a continuous line, and were of uniform size in the main flow, weighing about 200 lb. each, although some were much larger, one weighing 450 lb. Branching off from the main deposit were side flows, where the boulders ran from 20 lb. down to small pellets the size of a pea and even smaller."

It appears from these descriptions that priceite follows the habit of a number of other borate minerals, that is, it grows in the form of lumps within an enclosing matrix. This is certainly the habit of alexite and seems to be that of colemanite, as well as of priceite and boracite. The mode of occurrence of priceite shows that it may have separated from, or grown by reaction with, perco-

lating ground-water. It may be assumed that the ground-water carried the boron required, probably in the form of boric acid, and that this acid reacted with an available base. There is no apparent reason why the borate mineral should have formed only at this particular locality in Curry county, for similar country rock is distributed over wide areas in this region; and there is no distinctive evidence of spring action on the Lone ranch that could not be duplicated at almost any other point in the vicinity. Van't Hoff found that sodium-chloride solutions have an influence in facilitating the separation of some of the calcium borate minerals, and there is a bare possibility that the spray of sea-water may have exerted some influence at this locality, but this suggestion is no more than a guess. There seems to be little to offer in the way of an explanation of the origin beyond the clues given in Daley's statements, until the deposit is reopened and an opportunity for further observation afforded.

LOCALITY OF THE DEPOSIT. The Oregon deposit of prismatic was found on a homestead property that is still known as the Lone ranch, in sections 15, 22, 23, and 26, T. 40 S., R. 11 W., Willamette meridian, as shown by the accompanying plat of the township. The deposit itself lies in the bluffs and lower hill-slopes at the mouth of Cresswell creek, only a few hundred yards from the sea. Cresswell creek and another similar stream a quarter of a mile south enter the ocean in a little cove that lies between two rocky headlands as shown in the half-tone. The old mine-dumps near the ranch-building are now largely obscured. The mine-buildings and the old warehouse that was used for the shipment of the borate are gone.

The locality is most conveniently reached by road up the coast from Crescent City, in northern California, to Brookings, Oregon, over a main route of automobile travel, a distance of about 30 miles. From Brookings it is necessary to follow the road that runs nearest to the coast, which is rather rough, crossing the ridge-points a short distance back from the shore; by this road it is about five miles to the mouth of Cresswell creek and the old mine-workings. Crescent City may be reached by automobile-stage either from Eureka, California, or from Grants Pass, Oregon.

HISTORY OF THE PROPERTY. The Lone ranch is said to have been homesteaded early in the 'sixties by John Cresswell, or by a predecessor from whom the property soon passed into Cresswell's possession. The tract now known by that name comprises about 1050 acres, and stands in the name of the Pacific Coast Borax Co., a subsidiary of the Borax Consolidated, Ltd., of London, the English concern that almost controls the borax industry of the world. No attempt has been made to work the deposit since 1892, the property being let at a nominal rental for sheep raising to a man who also acts as caretaker. The history of the discovery of borate on this property and of the manner in which the early work was done is a record of significance both as to the mineral character of the deposit and its economic value.

Lieutenant Chase states that farmer Cresswell's attention was early called to an outcrop of a white substance, which he called chalk, on the banks of the stream that entered the sea from his property, where he found it in a caving bluff exposed by winter floods. This, he says, was about 500 yards from the sea and 20 feet above it. The 'chalk' was used by the coopers at the fisheries on Rogue river and the carpenters in the neighboring towns. The material also acquired a reputation as an excellent

POSITION OF LONE RANCH DEPOSIT IN OREGON

polishing powder for silver. Study of the mineral in San Francisco about this time proved it to be a borate, and the records of its occurrence were published. Apparently no practical significance was attached to the discovery.

About 1890, Cresswell sold his homestead rights to Denis Tryon for \$10,000. In the same year an Englishman named Fleming, who had had some experience with borax, came upon the records of this mineral in San Francisco; and, going to the Lone ranch, obtained an option for the purchase of the property from Tryon, good for six months, for the sum of \$25,000. Fleming

then put two men to work to open the deposit, soon finding a considerable body of the mineral. He allowed his option to expire, however, and the property was purchased by Walter W. Gray, acting in behalf of the Pacific Coast Borax Co. Gray then managed the development of the property, employing the miners by day's pay. A number of tunnels were run into the bank on the south side of Cresswell creek, near the locality where the first exposure had been found, but the results seem to have proved not wholly satisfactory, as this mining was referred to later as having been expensive and unprofitable and was not continued long. When the company discontinued work there were a number of miners or prospectors at the property, and they were told that if they could find an unopened portion of the deposit on the property a contract would be made with them to mine and deliver the mineral at a price per ton to be agreed. Several undertook the search, but most of them finally gave it up without success. One man, however, James C. Christensen—'Chris Christensen'—fared better than the rest and dug into a promising body of ore in the hill-slope north of Cresswell creek, almost opposite the bank where the other work had been done. In April 1891, Gray, acting as agent for the borax company, entered into a contract with Christensen, agreeing to pay \$23 per ton for such ore as he should mine and deliver for shipment at the seashore on the property and specifying a certain tract, about three acres in extent, within which he should be permitted to operate. Work was started soon after the contract was signed, and the following shipment, aggregating about 580 short tons, are recorded as having been paid for under this agreement:

1891	Prior to October (approximately) . . .	30 tons
	Oct. 2	42,088 pounds
	Nov. 30	50,862 "
1892	Jan. 30	90,987 "
	Apr. 18	86,621 "
	May 31	102,516 "
	Aug. 17	182,872 "
	Sept. 26	143,109 "
	Oct. 19	99,450 "
	Nov. 23	300,396 "

Christensen showed by testimony in a suit that during the last 30 days of operation under the contract he had taken out 150 tons of ore at a total cost to him of \$1100 for wages and board of the miners, so that he figured his cost of mining at less than \$10 per ton. Evidence was given by several of the miners who had worked on the property for Christensen that the ore in sight at the time the work was stopped, within the three-acre tract covered by the contract, was sufficient to have permitted production at about the same rate for two or three years. Thus there is specific evidence available as to the probable reserves in this portion of the deposit.

OTHER DEPOSITS. This deposit is of interest not mainly because it appears to represent a unique occurrence of borate mineral, but for the suggestion it carries that there may be other deposits of the same type which have perhaps been overlooked. Country-rock similar to that in which the priceite is found in Curry county is widely

distributed along the Pacific coast and elsewhere; and, if the borate has any genetic connection with the serpentine rock in which it has been found, other deposits might be discovered by ascertaining the clues by which they should be recognized. If prospectors find white chalky deposits in places similar to that described above they should have their specimens tested for borate, in the hope that valuable deposits of this substance may be found.

THE annual world production of tin prior to the War was from 120,000 to 125,000 tons, and, as far as can be gathered, the average annual production for the three years ended 1916 was 123,000 tons, of which the British Empire produced 54.5%, states the Chamber of Commerce Journal in quoting from an article in the Bulletin of Indian Industries and Labor. The Federated Malay States furnished the largest contribution both to the Empire and to the world's supply; in 1918 the output amounted to 37,370 tons. For the same year it is estimated that Burma turned out ore containing at least 1261 tons of metallic tin. The imports of tin into India during 1918 were 1229 tons. This shows, says the Journal, that Burma is capable of producing sufficient tin to make the Indian Empire self-supporting as regards this metal, provided the ores be smelted in India. The question of tin smelting on a large scale in India has recently received wide attention in view of the increasing production of ore; but it is doubtful if it could be developed profitably on a large scale at present, unless supplies were received from outside sources to augment the domestic production. In any case competition with the great and old-established businesses in the Straits Settlements, drawing their supplies from all parts of the world, would have to be faced. It is pointed out that the potentialities of the Tenasserim division of Lower Burma as a tin-producing region are fairly well known, but much remains to be done in the better equipment and further development of the deposits. Alluvial deposits especially offer attractive possibilities, and the officers of the Geological Survey of India have repeatedly drawn attention to areas which they considered worth the cost of testing. In the more isolated portions of Amherst, Tavoy, and Mergui districts, lying between the regions where deposits of both tin and tungsten ores are worked, the searches of the prospector should be especially directed to the margins of the great granite intrusions for veins carrying cassiterite, and to the valley gravels and sands of the middle and lower courses of the streams which drain them for alluvial deposits of tinstone.

CHROME ORE has been mined at several places in New Caledonia, but present production is limited to the Tiebaghi mine, Paagoumene, which is the richest mine in the country and one of the most productive in the world, states the 'Board of Trade Journal'. Other deposits have been worked at La Conlee, Plum, and Carenage, all near Noumea, and at the Vereingetorix mine in Unja, which is now exhausted.

The Danger of Storing Carbide With Explosives

By Charles E. Munroe

On March 14, 1921, an explosion occurred at about 6:15 a.m. on the premises of an iron-mining concern, through which two magazines, one containing upward of 9000 lb. of high explosive of the dynamite class, and a second, 60 ft. distant, containing upward of 10,000 No. 6 detonators, were completely destroyed, and a 'crater', 7 ft. deep by 30 ft. in diameter, was excavated in the ground at the place where the magazine containing the high explosive had been situated.

As a rule, any eye-witnesses to the circumstances immediately preceding and directly concurrent with accidental explosions are victims of such explosions, and, therefore, the conclusions reached as to the cause of such explosions must, perforce, be based almost completely on circumstantial evidence. In this instance, because both the explosive and detonators were of approved character; because of the time of the day and the state of operations at the time of the explosion; because the remoteness of the location of the magazines, on the side of a ravine, easily admitted of unobserved approach; because differences existed, and because no obvious cause was at once apparent, there arose suspicion that the explosion was not accidental.

Further investigation and review of the circumstances developed the fact that two full drums of calcium carbide had been stored in the magazine containing the high explosive, and that there was a newly opened box of the explosive placed beside a can of the carbide. Also that between 4:30 and 5 a.m. a watchman had entered the magazine and filled his canister with carbide, being careful to leave the carbide lamp he carried on the outside of the magazine while doing so, and that therefore he was compelled to work more or less "in the dark" while opening and closing the carbide drum and filling his canister. He wore at the time a 'slicker' coat, and hat, and, from the reports of the U. S. Weather Bureau of that date, it appears that rain began to fall at 1 a.m. and continued till 5 a.m. with a precipitation varying from "faint" to 0.07 in. It was possible, therefore, that, "working in the dark", some carbide may have been spilled, possibly upon the explosive in the open box, and that water may have been shed from the watchman's hat and coat. It is evident that there was much moisture in the atmosphere about the magazine.

A somewhat extended search reveals no record of any accident attending the storage of carbide with explosives or of any investigation of the possible effect of carbide upon explosives; but something may be learned as to the propriety of storing them in proximity to each other from a consideration of the known properties of calcium carbide; its observed behavior in storage, trans-

portation, and use; and reports of accidents to which it has given rise.

Calcium carbide as it appears in commerce is a dark crystalline substance with a metallic lustre and is quite hard. It is produced in electric furnaces by heating an intimate mixture of lime and coke, or other form of carbon, to above 3000°C. When pieces of carbide are thrown into water a bubbling or 'boiling' of the water takes place and a gas rises from the water which is easily ignited and burns with a luminous smoky flame. This effect is due to the calcium carbide reacting with the water to produce calcium hydroxide and acetylene. A similar reaction takes place when calcium carbide is exposed to air containing moisture, as air usually does; hence, unless the carbide is stored in air-tight vessels, acetylene is set free and the carbide is eventually decomposed, or 'spoiled'.

From the above it is apparent that acetylene is an inflammable and combustible gas. It is one of the most easily ignited of the inflammable gases, for when heated in contact with air it takes fire at 480°C. Like all other combustible gases and vapors, acetylene forms explosive mixtures with air and is unique in that so far as known it forms a wider range of combustible and explosive mixtures with air than any other gas. Hence, as in the case of any combustible gas, special care should be exercised to prevent acetylene escaping into the air to form such mixtures.

Moreover, acetylene differs from other gases in that during its formation it absorbs heat, therefore falls into the class of chemical compounds styled endothermic compounds. When acetylene is under a pressure of more than 15 pounds per square inch above the atmospheric pressure it can be detonated and it thus becomes a true explosive. For this reason no one should attempt to compress acetylene, certainly to not more than 15 lb., unless it is simultaneously absorbed by acetone, or other proper solvent, and some approved form of porous material. A process for the compression of acetylene has been developed, but it is highly technical and should not be attempted by the inexperienced.

Attention has been called to the fact that calcium carbide and water react to form calcium hydroxide and acetylene. It should be added that this reaction is accompanied, as very many chemical reactions are, with the evolution of heat, the temperature that is realized being dependent on the proportions of the carbide and water, the rate of mixing and the circumstances determining the rate at which the heat set free may escape.

Attention has also been called to the fact that calcium carbide is prepared by heating lime with coke in an electric furnace. Lime is produced by 'burning' natural limestone. It is well known that no substance occurs

*Reports of Investigations, U. S. Bureau of Mines.

pure in nature and that all rock is a mixture of minerals. Therefore, though limestone consists chiefly of calcium carbonate, it often contains a proportion of calcium phosphate which is reduced in the electric furnace to calcium phosphide. Hence calcium carbide has contained, and, unless proper care is taken in the selection of the raw material for its manufacture, may contain, calcium phosphide.

Calcium phosphide is a dark rock-like solid which when thrown into water produces a turbulent reaction, with the evolution of gaseous hydrogen phosphide, and this gas as it issues from the water and comes in contact with the air becomes spontaneously inflamed and burns with a faintly luminous flame and the production of a considerable quantity of white smoke, usually in the form of vortex rings. When calcium carbide containing calcium phosphide comes in contact with water, acetylene and hydrogen phosphide are evolved together and should the phosphide be evolved in sufficient quantity to become inflamed it would ignite the acetylene.

The calcium-carbide industry has, since the invention by T. L. Wilson, in 1892, of a practical method for making it, become of commercial importance, and in the development of its manufacture it has been found that to secure the best yields and highest economic results the raw materials used must be of the highest purity. It is claimed that the manufacturers now so carefully select or purify the materials entering into the manufacture of calcium carbide that acetylene produced from it contains only a safe minimum of foreign substances. It is well, however, to bear in mind that carbide forms a most attractive means whereby to store and transport for use elsewhere the energy of remote water-power, while through conversion into cyanamid it supplies a convenient means for so fixing the free nitrogen of the atmosphere that it may be employed in agriculture, in chemical manufactures, and in explosives. There is, therefore, continued chance of carbide appearing from new sources of manufacture in which less pure raw materials have been used. It has been pointed out that calcium carbide is hard. It is so hard that it may strike fire with steel.

The above discussion indicates a variety of ways in which accidental ignition or explosion may occur with commercial calcium carbide. Since it has become a commercial article there have been numerous reports of such accidents. Those interested in investigating the particulars are referred to the Annual Reports of His Majesty's Inspectors of Explosives in which, since 1900, there has appeared a record of them.

From what has been said it is evidently unsafe to store carbide in the same magazine with explosives or in close proximity to them. Moreover, such storage violates a fundamental rule of practice governing explosives magazines, which is:

Nothing but explosives should be stored in an explosive magazine, and preferably but a single class of explosives; for explosives of different classes may affect one another unfavorably when stored together. Detonators, caps, fuse, and all other mediums of ignition or detonation should be stored at a distance from explosives.

Nickel

The larger part of the world's production of nickel comes from the famous pyrrhotite-chalcopyrite ores of the Sudbury district in Canada, states a U. S. Bureau of Standards bulletin. These ores are at present smelted and refined by three processes, the larger tonnage being smelted in Canada and refined both there and in the United States by the Oxford process. A natural alloy, monel metal, is produced from the same ores by roasting and reducing the copper-nickel matte shipped to New Jersey from the Canadian smelters. Nickel is produced in the United States in several commercial forms, the greater tonnage in the form of 50- or 25-lb. ingots, or pigs, which are used in the manufacture of nickel-bearing alloy-steels. Nickel-shot and electrolytic-nickel cathodes are produced for the use of the manufacturers of non-ferrous nickel alloys, nickel-silver and cupro-nickel. Malleable nickel—sheet, strip, rod, and wire—is produced for stamping, fittings, resistance and pyrometer wire, spark-plug points, and kitchen utensils. Nickel castings are produced for the chemical industries for use against corrosive solutions. Nickel is generally useful by reason of its anti-corrosive properties. Monel metal is produced in the usual commercial forms—castings, rod, sheet, or wire—and is valuable because of its resistance to corrosion, its strength at high temperatures, and its resistance to the erosive action of super-heated steam (in turbines and steam-valves).

Besides the nickel or nickel-chromium alloy-steels containing from 1 to 3.5% nickel and largely used for automobile and ordnance construction, a number of other nickel-bearing alloys have interesting and commercially useful properties. Nickel-silver, containing from 52 to 80% copper, 10 to 35% zinc, and 5 to 30% nickel, is used in sheet form for the base metal for silver-plated household ware and other stampings and fittings, in the wire form for resistance wire, and in the cast form for automobile hubs. Cupro-nickel, containing about 15% nickel, the remainder being copper, is used for the manufacture of small-arms bullet jackets. Constantan, containing about 45% nickel, the remainder being copper, is used largely for resistance and pyrometer wire. Ferro-nickel, or 25 to 35% nickel-steel, is used as resistance wire and as Invar having a low coefficient of thermal expansion. Nichrome, and similar alloys, containing from 60 to 80% nickel, together with chromium and iron, is used for resistance wire and as a heat- or temperature-resisting alloy. Manganese-nickel alloys, containing from 2 to 4% manganese and the remainder nickel, are used largely for the manufacture of gasoline-engine ignition points, or spark-plugs.

FERRO-VANADIUM is made in the electric furnace or by the aluminum reduction or thermit process, according to an Arizona State Bureau of Mines bulletin. The carbon content of that made in the electric furnace is greater than in the alloy produced by the aluminum-reduction process. It is claimed that ferro-vanadium produced by the former method also contains vanadium carbide.

Book Reviews

Economics of Petroleum. By Joseph E. Pogue. John Wiley & Sons, New York. 375 pp., ill. For sale by 'Mining and Scientific Press'. Price, \$6.

The author of this volume is of the opinion that the United States is facing a critical shortage of crude petroleum, and that the coming year will see sensational developments in the industry. The United States, he says, has maintained a rapidly mounting supply of petroleum during the past few years because of a remarkable coincidence of circumstances that the years ahead give no promise of duplicating. Between 1915 and 1920, the petroleum industry absorbed over three billion dollars, the investment of this sum giving rise to an unprecedented expansion that stimulated production to such a degree that the peak of output was projected into the middle of the period of industrial depression in 1921. Coupled with this rapid expansion from within, the termination of the Great War made available sufficient tanker facilities to open up the cumulative results of a ten-year drilling campaign in the oil-fields of Mexico. Mexican oil, in consequence, flooded the American market, at the same time that domestic production was reacting upward from the stimulus of the vast sums of new capital that were being invested in oil production. Such was the situation at the beginning of 1921, soon after which the price of oil tumbled in the face of a temporary slump in demand. Pool after pool in the Mexican fields went to salt water, some over-night. Profits on domestic oil-field development were reduced, and drilling declined. Demands are now increasing; but the author asks where the needed increases in oil supply are to come from. The exploitation of foreign fields will be facilitated, but the question still remains unanswered.

Since its inception, the output of the American petroleum industry has expanded at an average rate of 8½% per year; during the past few years this rate has increased to about 10%. In 1921 the United States will consume almost 510 million barrels of crude petroleum; 1922 will probably see a consumption of at least 550 million barrels. With domestic production on the decline and with the output from Mexico being strongly curtailed, there can be but one result according to the author of this book—rising prices and a stringency in supply. The reserves of petroleum are limited in quantity, and the rate at which the supply may be brought to the surface is falling behind the rate at which the demand for oil is growing. The author discusses, in perspective, the more important economic facts relating to the present situation, and endeavors to interpret the changes that are taking place rapidly. The book is designed to be of service to the business man, the engineer, and the practical worker, not only in the petroleum industry, but in those industrial fields that are dependent upon the products of petroleum. The contents are as follows: I. Economic organization of the petroleum industry. II. The resource situation. III. Trend of oil-field development. IV. Trend of oil production. V. Transportation of crude petroleum. VI. Trend of refinery practice. VII. Analysis of refinery capacity. VIII. Outlook for oil refining. IX. Gasoline. X. Kerosene. XI. Fuel oil. XII. Lubricating oils. XIII. Petroleum by-products. XIV. Natural gas and natural-gas gasoline. XV. Marketing of petroleum products. XVI. Analysis of the exports of crude petroleum. XVII. Prices of petroleum and its products. XVIII. Relation between price and production of crude petroleum. XIX. Bearing of automotive transportation upon the oil industry. XX. Cracking. XXI. Composite motor fuels. XXII. Motor-fuel problem. XXIII. City-gas problem. XXIV. International aspects of petroleum. XXV. Mexico as a source of petroleum. XXVI. Relation of the coal industry to the oil industry. XXVII. Oil-Shale.

XXVIII. Utilization of petroleum. XXIX. Function of statistics in the petroleum industry.

Metric Versus the English System of Weights and Measures. Research Report No. 42, issued by the National Industrial Conference Board and published by the Century Co., New York. 261 pp., paper. For sale by 'Mining and Scientific Press'. Price, \$2.50.

This volume deals with a question of vital and timely importance, not only to the industrialist, but also to every citizen of the United States: shall the metric system be substituted by compulsion for the English system of weights and measures in this country? Agitation toward this end has been carried on during many years, and bills for the compulsory adoption of the metric system have, from time to time, been introduced in Congress. A measure is now before the House and Senate. Because of the importance and far-reaching economic bearings of the subject, the National Industrial Conference Board has prepared this report in order that American industry might be aided by a clear presentation of facts and arguments in determining what its attitude should be toward the proposed change in systems. The report is presented in three parts. The first deals with the history and the present national status of the English, metric, and other systems of weights and measures, respectively. The second part analyzes the application of the English and the metric systems to various specialized fields, such as science, engineering, manufacturing, and trade. The third section sets forth in a judicial manner, without taking a position one way or the other, the arguments advanced by advocates of the English and the metric systems, respectively, for and against the compulsory adoption of the metric system by the United States. The Board was fortunate in being guided in its work by an able advisory committee, composed of men of broad business experience and scientific attainment. This committee consisted of E. M. Herr, chairman, the president of the Westinghouse Electric & Manufacturing Co., Fred J. Miller, a past president of the American Society of Mechanical Engineers, Henry D. Sharpe, the treasurer of the Browne & Sharpe Manufacturing Co., Henry J. Towne, the chairman of the Board of Directors of the Yale & Towne Manufacturing Co., and Frank O. Wells, a former president of the Greenfield Tap & Die Co. These gentlemen have approached the subject from different viewpoints and with differing sympathies in respect to the problems involved; their opinions evidently have been of valuable service in keeping the presentation properly balanced. The report is an accurate and comprehensive collection of information on an important but little-understood subject, and an impartial synopsis of arguments both for and against the proposal that the metric system be adopted in place of the existing system of weights and measures in the United States.

Automotive Repair. By J. C. Wright. John Wiley & Sons, New York. 530 pp., ill. For sale by 'Mining and Scientific Press'. Price, \$3.50.

This book meets the need of the man who is expected to make general repairs and to keep the car in operation, whether he be a repairman or an owner. Emphasis is placed on actual repair jobs, rather than on the theory of design or detailed types of construction. The text in Part I covers the principal repair jobs that the general repairman or owner will be called upon to perform. Part II covers the principles of construction and operation that the repairman and owner need to know in order thoroughly to understand automotive equipment. It is stated that a thorough training and understanding of the repair work included in this book will guarantee an experience covering at least 95% of

the problems that may confront the general repairman or owner. The matter in Part II is of such a character that it is more than sufficient to enable him to understand the theory of gas engines and its application to automotive repair work. The book is excellently illustrated throughout with a large number of explanatory figures. The practical jobs discussed in Part I include 40 under 'Chassis Work'; 23 under 'Engine Work'; 26 under 'Electrical Work'; 20 under 'Trouble Shooting'; and 9 under 'Body and Radiator Work'. Part II discusses the chassis and its construction, automotive engines, lubricants and lubricating, electricity applied to automotive equipment, ignition, starting and lighting, engine fuels, carburetors, the cooling system, tires and tubes, and sundry useful information.

Oil Shales. By H. B. Cronshaw. John Murray, Albemarle street, London, W. 80 pp., paper. Price, 5s.

This is another of the monographs that are being prepared under the direction of the Mineral Resources Committee of the Imperial Institute, with the assistance of the scientific and technical staff. Only recently, when the demand for petroleum has so enormously increased and there seemed to be a danger of exhaustion of supplies of natural oil, attention has been directed to other sources of supply, particularly in regard to oil shales, which are rich in bituminous substances and yield oil and gas on distillation. Oil shales have been worked for the production of oil for a number of years in Scotland, France, and a few other countries; lately the deposits of the Kimmeridge Clay in England have been receiving attention, and those in Norfolk are under development. Much research has also been undertaken on the vast oil-shale deposits in the United States, especially in connection with those of Utah, Colorado, and Wyoming; those at De Beque, Colorado, are being actively developed. The monograph under review describes oil shale and the substance torbanite; the mining and distillation of oil shale; and the composition and properties of shale-oil. Descriptions follow of deposits of oil shale and torbanite in various parts of the British Empire, including those of the Utrecht district of Natal, the Wakkerstroom district of the Transvaal, Albert county in New Brunswick, Pictou county in Nova Scotia, Blue Mountains in New South Wales, and the Mersey district in Tasmania. Accounts of non-British deposits are also given, and include those of the United States, France, Bulgaria, and Brazil. A map showing the oil-shale deposits of the world and a bibliography conclude the volume.

Lubricating and Allied Oils. By E. A. Evans. E. P. Dutton & Co., New York. 128 pp., ill. For sale by 'Mining and Scientific Press'. Price, \$4.50.

This is one of the D-U, or directly-useful, technical series. It is explained that technical books of the past have arranged themselves largely under two sections: the theoretical and the practical. Theoretical books have been written more for the training of college students than for the supply of information to men in practice, and have been filled with descriptions of an academic character. Practical books have often gone to the other extreme, omitting the scientific basis upon which all good practice is built, whether discernable or not. The books in the D-U series are intended to occupy a midway position. The information, the investigations, and the discussions are to be of a directly useful character, but must at the same time be wedded to that proper amount of scientific explanation that alone will satisfy the inquiring mind. As stated in the foreword, the actual user of lubricating oils has been handicapped in the past because of a want of guidance, and has had to draw upon his own experience and that of his friends, or rely on the advice of the oil manufacturer, which though good in the main often

leaves much that is lacking. The present treatise aims to indicate the fundamental considerations in the selection of a good lubricant. The author is an engineer whose experience in all branches of the subject enables him to write as an authority. The contents of the book are as follows: I. History of petroleum. II. Oil refining. III. Occurrence of fatty oils. IV. Physical tests. V. Chemical tests. VI. Oxidation of petroleum. VII. Oleography. VIII. Lubricants. IX. Oils employed. Appendix.

Oil and Gas Rights. By R. S. Morrison and Emilio D. de Soto. Bender-Moss Co., San Francisco. 1115 pp. For sale by 'Mining and Scientific Press'. Price, \$10.

As stated in the preface, the passage by Congress of what is known as the Oil and Gas Leasing Act, by which all deposits of coal, phosphate, sodium, oil, oil-shale, and gas were withdrawn from the public domain, and the disposition and control of such deposits taken over by the Government under regulations promulgated by the Secretary of the Interior, suggested the necessity for this work. It contains the latest decisions and principles concerning the rights of the owner in fee of lands not affected by the Act, containing oil or gas lands, the rights of lessors and lessees, and of all persons who have contracted relations concerning the same; and treats of the various topics and subjects incident to the laws governing the owning, leasing, production, sale, and transportation of oil and gas, with the latest text of the statutes of the States that have legislated upon oil and gas rights. A full text of the Oil and Gas Leasing Act is given, with an analysis of its provisions. An attempt is made to interpret those sections in which the meaning is in doubt; and the latest decisions of the Department construing some of the provisions of the Act are given. The book concludes with a number of useful forms and a glossary.

Recent Publications

Gold, Silver, Copper, Lead, and Zinc in Idaho and Washington in 1919. Mines Report. By C. N. Gerry. 1:19, U. S. Geological Survey, 1921. 46 pp. From Mineral Resources of the United States, 1919, Part I.

Deposits of Manganese Ore in Montana, Utah, Oregon, and Washington. By J. T. Pardee. Bull. 725-C, U. S. Geological Survey, 1921. 103 pp., ill. From Contributions to Economic Geology, 1921, Part I.

Geology of the Cement Oil Field, Caddo County, Oklahoma. By Frank Reeves. Bull. 726-B, U. S. Geological Survey, 1921. 45 pp., ill., maps. From Contributions to Economic Geology, 1921, Part II.

Contact-Metamorphic Tungsten Deposits of the United States. By Frank L. Hess and Esper S. Larsen. Bull. 725-D, U. S. Geological Survey, 1921. 64 pp., ill. From Contributions to Economic Geology, 1921, Part I.

Deposits of Chromite in California, Oregon, Washington, and Montana. By J. S. Diller, L. G. Westgate, and J. T. Pardee. Bull. 725-A, U. S. Geological Survey, 1921. 84 pp., ill. From Contributions to Economic Geology, 1921, Part I.

Mineral Resources of Alaska. Report on Progress of Investigations in 1919. By Alfred H. Brooks and others. Bull. 714, U. S. Geological Survey, 1921. 237 pp., index, maps. For sale by Superintendent of Documents, Government Printing Office, Washington, D. C. Price, 35 cents.

REVIEW OF MINING

DATE OF INSTITUTE MEETING CHANGED

The meeting of the San Francisco Section of the Institute that was announced for December 29 has been postponed one week until December 27. H. W. Morse will read a paper on the 'Present Status of the Treatment of Mixed Copper Ores'.

TERMS FOR THE MERGER OF ANACONDA COPPER MINING CO. WITH AMERICAN BRASS CO.

A plan was formulated in New York on December 15 by directors of the American Brass Co. meeting with C. F. Kelley, president of the Anaconda Copper Mining Co., and Charles F. Broecker, chairman, whereby American Brass stockholders will shortly be offered the option to dispose of their shares to Anaconda for \$150 in cash and three shares of Anaconda against each share of American Brass.

At this price the \$15,000,000 capital stock of American Brass, if purchased in its entirety, would cost Anaconda in cash and stock \$45,000,000, and of this \$22,500,000 would be cash. If control passes to Anaconda it will mark one of the most important steps in the evolution of the brass and copper business. Anaconda has been drawing wire and rods at Great Falls for some time and has been able to command the Pacific Coast market by reason of advantages over the Eastern manufacturers in the matter of freight and other charges. American Brass stock during the past few weeks has risen from around \$165 per share to just under \$300. Arthur Curtiss James has long been one of the largest individual stockholders. Significance attaches to this statement when it is realized that Mr. James also figures as one of the heavy holders of Phelps Dodge Corporation, of which he is vice-president. Cleveland H. Dodge, another vice-president, has also an important ownership in the Brass company.

NEW IDRIA QUICKSILVER MINING CO. IS GIVEN JUDGMENT FOR LARGE SUM

A verdict for \$1,803,364.05 was awarded the plaintiff at Providence, Rhode Island, on December 16, in the suit of the New Idria Quicksilver Mining Co. of California against the British-American Manufacturing Co. of New York in the United States District Court there. The verdict followed ten days of testimony in the \$2,500,000 suit of the New Idria company, which alleged that the British-American company had entered into a contract with the plaintiff company for the purchase of about 11,000 flasks of quicksilver, but had failed to fulfill the agreement.

GRANBY CONSOLIDATED MAKES 11-CENT COPPER

The recent wage-reduction and the institution of various operating economies are finding reflection in the cost sheets of Granby Consolidated Mining, Smelting & Power Co. of British Columbia. The company is at present laying its copper down in New York at a total cost, before taxes, of 11c. per pound. This compares with average cost in the early months of this year of 12½ to 13½c. per pound and means that Granby can make a modest profit even on the present relatively low price for copper. Granby is one of the few mines that remained in operation when over 90% of the country's copper companies suspended production in April

of this year. In the first six months of 1921 the company ran behind about \$300,000, but with the turn of the half year and the full effect of its wage-reduction being felt, the figures have been getting larger on the profit side of the ledger. In the nine months to September 30, Granby produced nearly 22,300,000 lb. of copper, indicating a production of inside 30,000,000 lb. of copper for the whole year. The company has sold metal during the past two months and its financial position shows improvement over that at the first of the year.

INCREASED PRODUCTION OF SILVER-LEAD ORE IS NOTED IN UTAH

A recent survey reveals the fact that production of lead in Utah is about 50% of normal. The largest lead producer in the State, the Utah-Apex property at Bingham, which has produced as high as 50,000,000 lb. per annum, has been closed since the early part of the year, when the price of the metal dropped below 5c. per pound. The Pittman Act is responsible for the large output of silver-lead ores from the Tintic and Park City districts. The Murray smelter reports that shipments of silver-lead ores have been increasing lately, and that three furnaces out of eight are in operation. It is probable a fourth furnace will be blown-in shortly. The United States smelter at Midvale has been running three furnaces out of seven since January 1. The International smelter at Tooele has been closed since July 1.

NIPISSING MINES CO. OPENS NEW OREBODY

On vein No. 64 the Nipissing Mines Co., of Cobalt Ontario, has opened a new body of ore that in places assays as high as 2000 oz. silver per ton over a width of approximately two feet, according to E. P. Earle, president of the company. The exact extent of this orebody has not yet been determined, but development is being concentrated on this work, as this is the biggest find in point of size made at Nipissing's property for some time. In the last two months the company has developed a body of high-grade silver ore on vein 251 at its No. 63 shaft. This vein varies in width from one to four inches and the ore contains from 2000 oz. silver to as high as 5000 oz. The management states that it does not as yet know the extent of this development, but as far as operations have progressed the grade has been maintained. To bring back its reserves to something like their former status, the Nipissing management has been concentrating on underground development. Having an abundance of working capital and with operating costs drawn down to a minimum, the company has been able to perform this extraordinary development work at a moderate expense.

STAR-FEDERAL CASE IN THE COEUR D'ALENE IS SETTLED OUT OF COURT

The litigation between the Star Mining Co. and the Federal Mining & Smelting Co., which has been in court for almost four years, was suddenly terminated on November 10, when formal announcement was made that an agreement had been reached by the litigants. The case was being tried before Judge F. S. Deitrich, of the United States District Court at Coeur d'Alene. The hearing was for the purpose

of determining the amount the Federal company should pay the Star on account of ore removed from the Star ground in the operation of the Morning mine, owned by the Federal. Under the terms of the agreement the Federal company pays the Star \$350,000 in full settlement for all ore removed and relinquishes all claim to the disputed ground. As if to clinch the transaction, the Federal also gives the Star an option for 90 days on the Iron Crown claim and that portion of the Grouse claim lying west of the west line of the Morning claim extended across the Grouse, practically half of the claim, for a consideration of \$100,000. The Grouse claim lies south of and alongside the Morning and Evening Star, the latter owned by the Star, and it was the right to the apex of the vein which is bisected by the side-line between Evening Star and Grouse that led to the litigation. A branch of the Morning Star vein extends through the Iron Crown claim, which joins the Grouse on the west. By taking over the Iron Crown and half of the Grouse, the Star becomes the owner of all the ground directly or indirectly connected with the litigation and is therefore protected from any possible cause of further dispute.

RENEWED INTEREST IN THE WARREN DISTRICT OF IDAHO

George W. Cooper, of Los Angeles, California, visited Warren, in Idaho county, Idaho, several months ago; he investigated the mining resources of the district and, after satisfying himself that there were immense deposits of gold and silver ore remaining yet untouched, he and his associates took a bond and lease on the Thomas Creek gold-placer property formerly owned and operated by Charles Curtis and W. P. Grindle. This property comprises an area of about 320 acres of land of which practically 290 acres is virgin ground which is estimated to yield better than 30c. gold per yard. The overburden ranges from approximately 6 to 18 in. of soil, leaving about 9 ft. of pay-dirt. One sample assayed, under date of November 17, 1921, by Smith, Emery & Co. gave the following results: 484.60 oz. of gold per ton, valued at \$10,016.68; it contained also 22 oz. of monazite sand per yard of dirt. The property will now be operated by the Co-Operative Mines Co. of Warren, Idaho, with headquarters at Warren. Several other companies are also organizing to develop and operate other properties in the spring. One of those companies will develop and operate a large deposit of monazite sand. Mesothorium is today known the world over as a substitute for radium, and the Warren deposit of monazite sand is considered to be the richest known deposit yet found in the West.

WESTERN BRANCH OF CANADIAN MINING INSTITUTE WILL MEET IN FEBRUARY

The Western Branch of the Canadian Institute of Mining and Metallurgy will hold its annual meeting at Vancouver during the first week in February. Some interesting papers will be read, among which may be mentioned 'The Geology of the Britannia Mine', 'Mining and Metallurgical Practice at the Britannia Mine', and a number of papers on the geology of and mining practice at the Vancouver Island coal mines. Owing to the continued high price of coal and the marked decrease in production, these collieries are attracting a considerable amount of attention.

SUBSTANTIAL REDUCTION IN STOCKS OF REFINED COPPER SINCE JULY 1

The Boston News Bureau has made a careful survey of all the factors entering into an analysis of the copper status—production, exports, and domestic consumption—and finds that since July 1 there has been a reduction in the stock of refined copper in this country amounting to almost 300,-

000,000 lb., or 40%. In other words, home meltings plus exports have exceeded United States production of refined copper by 290,000,000 lb. Of course, this is an estimate, but it is arrived at after painstaking investigation, conferences with large producers and refiners as well as with copper consumers.

The figures are as follows, based on actual and partly estimated returns (in pounds):

U. S. stocks of refined copper on July 1, 1921.....	750,000,000
U. S. production of refined from July 1 to November 30, 1921.....	225,000,000
Total	975,000,000
U. S. consumption, July 1 to November 30, 1921.....	250,000,000
Exports from July 1 to November 30, 1921.....	165,000,000
Total	415,000,000
Estimated visible supply, December 1.....	460,000,000
Stocks of blister copper, December 1.....	165,000,000
Total	625,000,000

A stock of 460,000,000 lb.—and this includes 325,000,000 lb. held by the Copper Export Association—while large, is not the threatening menace which our surplus stock on January 1 last appeared to be. Our big producers are still closed down tight, and it would take many months to get them back to their normal stride even were resumption orders issued immediately. To the visible supply of 460,000,000 lb. must be added 165,000,000 lb. of potential product or semi-finished material known as pig- or blister-copper. This crude product is at the refineries awaiting treatment. It is material which has been mined, smelted, and transported to the Eastern seaboard awaiting the finishing process by which it is made into marketable copper.

The figures above do not include stock in process—en route to or in the refining-vats—beyond the 165,000,000 lb. of accumulated matte above referred to. The 'billion-pound surplus' of a year ago now shrinks to 625,000,000 lb. of visible supply, and of this amount only 460,000,000 lb. is available for immediate delivery, with 300,000,000 lb. or thereabout ear-marked for export. Of course, the latter must be included in any estimate of the available world supply.

PROPOSED SUBSTITUTE FOR ELECTRIC POWER.

Representatives of a Swedish engine company offer a solution of the power problem in Northern Ontario which is interesting some of the mine managers. They propose to supply oil-engines of size sufficient for the largest mines at an initial cost for installation of \$125 per horse-power, with a guarantee that power can be produced by fuel-oil at \$40 per horsepower-year, which would be a considerable saving over present hydro-power rates. One drawback is that it would take a year to make delivery and complete installations.

COLUMBIA SECTION OF THE INSTITUTE TO MEET AT SPOKANE

The eleventh annual meeting of Columbia Section of the A. I. M. & M. E. will be held at the Davenport hotel, at Spokane, on December 28. The nominating committee has submitted the following names of members for officers for the coming year: Rush J. White, of Wallace, Idaho, for chairman; Frank M. Smith, of Spokane, for vice-chairman; and L. K. Armstrong, of Spokane, for secretary-treasurer.

ARIZONA

Ajo.—The New Cornelia Copper Co. has resumed shipments of copper to the East. Shipments will remain for the present at about one car per day. Production still continues at about 1,500,000 lb. of copper per month.

Jerome.—In a recent interview given at Jerome with Charles W. Clark, general manager for the United Verde

Copper Co., he stated that conditions of the copper-metal market at present pointed to a resumption of operations at the United Verde mine and smelter some time in February.

Morenci.—Walter Douglas, president of the Phelps Dodge Corporation of New York, stated, just prior to his recent departure from Morenci for New York, that the output of the No. 4 concentrator at Morenci will be doubled as one means for alleviating unemployment in this district. The mill will be remodeled and increased in size, he said. On December 26 the Phelps Dodge company will take over the holdings of the Arizona Copper Co., according to Douglas, and mining operations of the newly acquired properties will be enlarged.

Oatman.—The mill of the United Eastern is handling 300 tons per day. About 70 tons of ore per day is coming from the Big Jim property, by tramway. The Tom Reed mill is closing a two-weeks' trial run, stopping to determine the accuracy of the sampling. For the period the mill has been handling 125 tons per day, about 25% above what had been expected. On resumption of operations there is to be custom service for ores of the United American and other Oatman properties. There is belief that this custom work will cause renewed activity in the Oatman section, where many mines have relatively small available amounts of ore from which enough profit might be secured to continue their work of development. The mill of the C.O.D. Mines Co. has been started, with daily consumption of about 60 tons of ore. Much of the ore is from the 500-ft. level, where the zinc content has been found much lower than in the upper workings. A. D. Storke is manager. Ben Bennot is in charge of mine operation and W. Rith is in charge of the mill.

Samples across a $\frac{1}{2}$ -in. seam at 40-ft. depth in an old shaft of the Enigma mine in Weaver district gave returns of 10 oz. gold and 1800 oz. silver per ton. Robert Good and Frank Hodge are working the mine under bond from its owner, W. O. Ruggles.

Superior.—It is rumored that the Queen Creek Copper Co. is negotiating for purchase of the holdings of the Grand Pacific Copper Co. The property lately was visited by Messrs. Mackay and Stephen, two Scottish capitalists also heavily interested in the Dundee-Arizona mine at Jerome. Grand Pacific has shipped a number of carloads of good ore from comparatively shallow workings.

Report has come from the Kay mine, 40 miles north of Phoenix of the finding of a large and rich copper orebody in an extension of the workings on the 800-ft. level. The property is in charge of George Long, one of the discoverers of the United Eastern at Oatman.

Willcox.—According to the latest report, the Central Copper Co. is employing 250 men in its development of the Mascot and Central properties in the Dos Cabezas district, 14 miles south of here. On hand, in cash and bills receivable, the company now has \$917,525, an increase of \$526,293 within a year. John W. Prout, Jr., manager, has opened 11 new orebodies during the year in the Mascot section, while the development in the Elma section is declared most gratifying. New hoisting equipment has been installed on the Mascot. The properties now have about 70,000 ft. of development. The Central is working 30 claims of its own and 56 held under a 20-year lease from the Mascot Copper Co., in all with an area of 1380 acres. Connection with the Southern Pacific at Willcox is by a broad-gauge railroad that had been built by the Mascot company.

CALIFORNIA

Colfax.—The tunnel of the Blue Channel mine at Iowa Hill, being driven by a syndicate of Pittsburgh capitalists, is now in 1800 ft. Lyman Gilmore, who is in charge of the work, states that patches of high-grade gravel have been found at intervals and that the expectation is that the solid channel should be reached within 600 ft. The channel-

system is presumed to be the same as that on which the Morning Star and Big Dipper properties were located.

Grass Valley.—It is announced that the Intermountain Development Co., of Salt Lake City, has purchased half the capital stock of the Bullion Exploration Co. and that the Bullion property will be re-opened at once. The group comprises 130 acres of good ground and covers about a mile of the Bullion and Union Jack lodes. Prior to 1900, the different properties were credited with a yield of \$1,000,000, one-half of which came from the Bullion Consolidated. Henry I. Moore and George Mainhart are officials of the new company.

Kelso.—The Quo Vadis mine, a former producer of rich gold ore, has changed hands and is to be worked in a more modern way. A new Rix air-compressor and 30-hp. engine,

In the Coeur d'Alene Region of Idaho

as well as four air-drills, have been purchased and are being installed. Housing for the machinery is now being erected. The ore is a 'sugary' quartz in quartz-porphyry and carries gold, silver, and lead with a trace of copper.

Randsburg.—The Silver Dike Mining Co. has permission from the Commissioner of Corporations to sell $1\frac{1}{2}$ million shares of stock at 20c. per share. Whenever shares are sold for cash the company is to issue to S. S. Rapp and associates a like number of shares up to 1,000,000 in exchange for the transfer of certain mining claims. The 1,000,000 shares to be issued to Rapp are to be deposited and held as an escrow. The company is permitted to pay 20% on the sale of its stock.

Sutter Creek.—W. P. Henry, president of the Central Eureka Mining Co., states that an extension of one year on

the payment of the deferred instalment on the South Eureka mine will give the company until February 1, 1923, before it will be necessary to decide on the advisability of making the payment. A new \$5-ft. all-steel head-frame and a large electric hoist are now being erected. The company hopes to have this new equipment ready to operate early in January and will then be in a position whenever it becomes necessary to sink the main shaft 1500 ft. below the new level that is now being opened.

Tower House.—Charles Garrett, Robert Garrett, and Jack Pepper are doing development work on the Double Header mine near this place. Charles Garrett located the mine a few years ago. Finding it was on railroad land, he bought it from the railroad company.

Tuolumne.—The Casa Madera Mining Co. has installed heavy machinery and is driving a 2000-ft. tunnel from the North Fork slope. Work will be continued throughout the winter.

COLORADO

Alma.—The Colorado Power Co. is extending its line through Alma to Fairplay, and constructing a branch up Mosquito gulch to furnish power to the Brownlow mines, now operated by Detroit capitalists, who are opening a good vein of mill-grade ore over 20 ft. wide, and other smaller veins of ore of better grade.—The Maseotte Tunnel Co. will continue operating this winter; a building has been constructed to house an electrically driven compressor. The company owns claims extending about two miles on each side of the course of the tunnel.—Teams from the London mine are keeping the trail open for hauling ore; sleds will be substituted later in the winter.—The Dolly Varden continues steady production of silver ore containing some gold and lead. Recent shipments have settled at from 60 oz. silver for second-grade to as high as \$340 per ton for first-class ore.

Aspen.—The Hope tunnel has been extended 40 ft. beyond the point where the new ore-shoot was cut, but to date the grade is low. A carload carefully sorted has been shipped.

Creede.—The Commodore mine has been leased and men are engaged cleaning out the No. 3 and No. 4 tunnels preparatory to taking out ore for shipment. The property has been leased by J. W. Wilson, and engineers who have examined the old workings; a large tonnage of both milling and shipping ore is in sight.

The Chipeta M. M. & S. Co. is extending the main drift on the H. A. C. property to prospect virgin territory and is rapidly gaining depth. It is planned to construct a mill near the railroad, to be connected by aerial tram when sufficient ore is blocked out.—Work has started on the Little Jessie, on Corbett creek; other claims of the Teller group are to be developed by the leasing company formed by Judge Pryor and associates at Aspen.

Georgetown.—A station is being cut in the Capital tunnel by the Gilpin Development Co., of Boston, preparatory to installing an underground hoist over the winze being sunk on a vein exposed in the floor of the tunnel. The Capital company mined good ore from a stope carried up 300 ft. above the tunnel-level, but no work has been done to date below the tunnel.—The Nicholls, an old silver producer in the 'sixties, which has been inactive for more than 50 years, is to be operated by local miners. Old-timers state that, when work last ceased, a vein of rich ore was showing in the bottom of the shaft and the last ore shipped returned \$430 in silver per ton.

Lake City.—A survey has been made and plans prepared for construction of a hydro-electric power-plant of 6000 hp. to supply power to the Golden Fleece properties. The company controls mining property and reservoir sites, including

Lake San Cristobal, with capacity of 30,000 acre-feet, necessary to the project.

Silverton.—Lessees on the Wyman group, on Anvil mountain, have opened a vein 6 ft. wide, carrying four pay-streaks 6 to 8 in. wide, at a depth of 700 ft. from the surface, sampling 80 to 100 oz. silver. The property is developed by tunnel, one mile from the railroad; it is accessible at all seasons, so that operations will start this winter.

IDaho

Coeur d'Alene.—Ore has been opened in several parts of the property of the Independent Lead Mines, which consists of 12 claims. In the Independence claim the Morning vein has been cut at a depth of 100 ft. and at a point 50 ft. east of the Federal line. The body is 15 ft. wide and contains high-grade carbonate and galena ore. Shipments are said to have been made from this exposure in earlier days. This vein is exposed in the Victor claim by a carbonate-iron blow-out at a point 3000 ft. from the scene of discovery.

The Ajax Mining Co. has started work on the mile of tunnel which it will drive at a cost of \$90,000 to reach a point directly under the ore-shoot in the upper workings. The tunnel, 6 by 8 ft. in the clear, has already been driven 260 ft. in somewhat broken ground that requires timbering, according to reports at hand. Two shifts of three men each are making 5 to 6 ft. each shift when not timbering.—In the Nellie mine in the Osborne district a rich ore-shoot has been discovered in the lower tunnel. The property is being worked by Peter Gardner and associates, lessees, who took it two months ago and already have shipped some good ore from the upper workings to the Bunker Hill smelter. The extent of the find is not determined, but it gives 300 ft. additional depth to the ore.

Four feet of ore has been opened on the 400-ft. level in the Chicago-Boston mine, two miles west of Wallace. Assays of the 4 ft. of ore returned 11.2% lead and 11.5 oz. silver; in the middle is about 1 ft. of ore that assays 48% lead and 42 oz. silver. The strike is 350 ft. east of the shaft and gives a depth of about 1200 ft. One carload of sorted ore has been accumulated from the 200-ft. level; it will be shipped to the Bunker Hill smelter. It is expected this ore will run about 50% lead. More of this ore will be mined from the 200-ft. level and these shipments are expected to pay a large part of the expense of development.

Pioneerville.—The Golden Age Mining Co. has opened a vein between 4 and 5 ft. wide at 295 ft. in a cross-cut on the 250-ft. level. A sample taken across the entire face assayed \$30 in gold and \$10 in silver. The company is drifting both ways on the ore and will soon start a raise to connect with the old workings above. Arthur W. Stevens is superintendent.

Priest River.—The Lucky Abe mine on upper Priest lake is developing splendidly. Three good veins traverse the property. One is said to be 80 ft. wide, carrying 8% copper, \$1 per ton in silver, and 85c. in gold. The tunnel is in 40 ft. Another vein, 30 ft. wide, is said to contain 100 oz. silver per ton. The vein has been cross-cut and the work is being done in the hanging wall. Assays of 26% copper and \$12 per ton in gold are reported from the third lode, said to be 22 ft. wide. Peter Chase, of Coolin, and Samuel Edelstein, of Spokane, are managers of the property.

MICHIGAN

Houghton.—Isle Royale is in a position to give a good account of itself when operations are resumed at that Calumet & Hecla subsidiary. The mine is well opened in ground that will run nearly 18 lb. per ton, the vein showing uniformity of content with depth. Powerful electric pumps, in No. 4, 5, and 6 shafts, have taken care of the water, and the mine is physically in good condition. Many of the former employees live at or near the mine, and the only delay, once

orders are given to start, will be that incident to the replacing of underground equipment and the overhauling of machinery. Some timbering will be necessary, but this is not expected to interfere seriously with actual mining work.

Isle Royale costs were high during the war years, running up as high as 16 ¢. per pound in 1920, but in common with other mines of the district, Isle Royale will benefit by a reduction of costs in every department when operations are resumed. The labor cost will be notably less and economies will be effected in purchasing coal and other supplies.

Construction of the new collar for Gratlot No. 2 shaft and base for the new hoist, preliminary to the resumption of sinking, is well under way. Shaft repairs will be undertaken as soon as the collar is complete. Surveys have been made for track extensions from the mine to the Mineral Range, over which shipments will be made to the Polnt Mills plant. Before production will be attempted on a large scale, however, it will be necessary to install a new hoist at the Seneca shaft. Opening work in Seneca continues in splendid ground,

normal drifting from it. There is exposed in the Eeklund-Paget group, one mile east of the Frances, a 33-ft. width of ore of an average value of \$14, according to Taylor. This ore is at a depth of 50 feet.

Austin.—Discovery of rich gold ore about three miles east of here has resulted in the location of over 30 claims and prospecting over a wide area. The original strike was made by Peter O'Brien while prospecting for the source of placer gold in this district. The quartz closely resembles the rich material found two years ago in the Birch Creek district, farther to the east.

Carson City.—S. S. Arentz and other Western Congressmen are endeavoring to secure a modification of the rules governing the purchase of silver under the Pittman Act, whereby the assay-office at Carson City can receive consignments of bullion for which they will pay at the rate of \$1 per ounce of contained silver. An allowance for express charges to San Francisco must also be made. Since the Pittman Act has been in effect, 'dollar' silver has been received only at

Mine and Mill of the Leadville Mines Co. at Gerlach, Nevada

The third level drift, north, with which Gratlot will be connected, shows no diminution in content. Considerable 'mass' is being encountered in all drifts.

Mohawk will finish the year with a production of close to 14,000,000 lb., equaling the 1916 output and greater than the production of any year since. It is understood to have no more than normal stocks of metal on hand, having managed to sell the greater part of its output from month to month. A full program of drifting and stoping is under way in all four operating shafts, while sinking is proceeding in No. 1 and 6 shafts. The yield holds well to the average of about 24 lb. per ton.

MONTANA

Helena.—Ten tons of float quartz from the Bamboo Chief claim, near Virginia City, netted the lessees \$1600 from the East Helena smelter of the American Smelting & Refining Co.—A car of silver-gold-lead ore is ready for shipment to the East Helena smelter from the Carbon Hill mine in the Grass Valley district. The ore assays about \$50 per ton.

Marysville.—The Barnes-King Development Co. is operating the Shannon mine at Marysville successfully. The Penobscot mine is being developed by an adit.

NEVADA

Argentite.—Drifts driven a total of 200 ft. from the bottom of the 100-ft. shaft on the Frances have been in ore of an average value of \$25 to \$30 for this distance, according to F. H. Taylor, manager, who says the average width of the ore is 6 ft. A three-drill air-compressor has been bought for sinking the shaft another 100 ft. and doing 300 ft. of addi-

San Francisco, Denver, and Philadelphia, the various Government assay-offices paying only the market price for the metal.

Gerlach.—A. A. Codd is planning more extensive development of the property of the Leadville Mines Co. During this year the gross production has been more than \$153,000, which is a good record, considering that shipments were not begun until after July 1. All of this production has come from between the 190- and the 300-ft. levels. Codd now purposes to sink to the 500-ft. level and begin drifting at both the 400- and the 500-ft. levels. The mill is well equipped and the ore is concentrated to about 6 into 1. This gives concentrates of about \$200 per ton. The mill is now handling an average of 35 tons per day, which will be increased to 50 tons. A new 75-hp. boiler is being placed, which will give the needed extra power.

Goldfield.—The Silver Pick has shipped two carloads of ore from an intermediate level between the third and fourth. This ore is in the extension of the orebody that was mined on the third level and in the winze. Ore also has been found in a drift driven 100 ft. north from the bottom of the winze.

Hornsilver.—Although the good conditions in the Orleans have not yet led to other work in the district on anything but a small scale, sales of groups of claims, the formation of companies, the presence of mining engineers from outside Nevada, and deals of various kinds indicate that there will be much activity in the spring and summer. With ore opened by drifts and cross-cuts for 300 ft. on the 600-ft. level, the Orleans company is now opening the 700-ft. level,

where the south-east drift has been driven 70 ft. In ore, a 30-in. width of which assayed \$100 for practically the 70 ft. The remainder of the width of the drift assays \$20. Among the engineers who have examined the mine recently are Roy H. Marks, with the United Verde Extension at Jerome, and F. E. Perry of Los Angeles.—Harry De Votie of Goldfield has sold control of the Hornsilver American company to E. G. Reinert, J. F. Erisman, and G. T. Hoffman of Denver. The company owns eight claims from which \$10,000 to \$12,000 worth of high-grade ore has been shipped, earload shipments assaying as high as \$70. The mine is well equipped with machinery at two shafts, one 200 ft. deep and the other 140.

Pioche.—Eastern and local interests have recently taken over a number of properties in the Silver Park district, situated about 45 miles north of here near the Atlanta gold mine, which is said to have a proved reserve of 100,000 tons averaging \$9 gold and silver. The mines include the Nevada Park, the Miner's Delight, the Great Eastern, and the Conway & Bradshaw properties, comprising the best of the mineral area. Besides these patented mines, the Fan Tan group of four claims has been acquired, giving sufficient territory for future mining operations. All these properties have been producers during the past few years. Only the former low price of silver and the excessive cost of transportation, which has rendered unprofitable the mining of ore, except such as is of bonanza grade, has held back the development of the district.

UTAH

Alta.—Assays of the orebody recently opened in the old Emma mine give returns of from 12 to 55% lead, and from 14 to 72 oz. silver per ton. The thickness of the deposit has dropped from 4 ft. to 14 inches in 12 or 14 ft. of drifting.

The Columbus-Rexall Consolidated Mines Co. is shipping an average of 250 tons of ore per month. Practically all of this production is coming from the No. 10 workings, close to the Cardiff line, and averages about \$40 per ton net. The company employs 18 men underground. Recently a new orebody was cut about 5000 ft. from the portal of the main tunnel. The Columbus-Rexall now has three openings into the Cardiff mine, which permit of better ventilation for both properties.

Boxelder County.—The new tunnel being driven at the Vipont Silver property is progressing at the rate of 200 ft. per month. As soon as construction now under way is completed, the mill will be in a position to treat 175 tons of ore per day.—The Utah-Idaho Mining Co., adjoining the Vipont, has installed a compressor and power-drills. Development will be carried on during the winter.—In the Golden Eagle property, a tunnel is being driven to explore ground in the vicinity of the Vipont boundary line.

Eureka.—The United States Smelting Co. has discontinued the mining of iron ore at the Dragon Consolidated property, due to an over-supply of fluxing material at the Midvale smelter.—Allison Brothers, of Heber City, announce that they will develop the Lucky Shepard property, in the western part of the district, near Desert mountain. Several years ago sheep-herders discovered a vein of high-grade silver-lead ore within a few feet of the surface.

Ore shipments from this district for the week ending December 10 totaled 176 earloads, as against 166 for the preceding week. The Tintle Standard shipped 61 cars; Chief Consolidated, 43; Victoria, 16; Dragon, 15; Iron Blossom, 12; Eagle & Blue Bell, 8; Mammoth, 4; Colorado, 4; Swansea, 4; Centennial-Eureka, 3; Plutus, 1; Showers, 1; Gemini, 1; Bullion-Beck, 1; Empire Mines, 1; Tintle Drain Tunnel, 1.

Work of overhauling machinery at the Grand Central property has been completed. Paul Hilsdale, who has taken the property under a lease and bond, states that 120

miners have applied for leases, while 60 applications have been granted. It is probable that within a month this number will be doubled. Hilsdale has three crews of surveyors at work, preparing new maps. A transmission-line has been built from the Chief Consolidated mine to the Grand Central, and when the necessary equipment has been installed, the surface machinery will be electrically-driven instead of operated by steam.

Milford.—Joseph F. McGregor, John Goodwin, and Earl Alverson, of Beaver, have taken a lease and bond on the old Moscow property, about 12 miles from here. Development work has been started, and a car of silver-lead ore has been shipped to a Salt Lake valley smelter.

Park City.—Ore shipments for the week ending December 10 totaled 2161 tons, as compared with 2068 tons the preceding week. The Judge allied companies shipped 1172 tons; Silver King Coalition, 527; Ontario, 463.

Development work has been carried on at the Revelator property in Snake Creek canyon during the past summer, according to Samuel Hair, who is in charge of the work. One shipment was made, and the second will go forward within a short time. In the Vassar No. 2 claim, owned by H. T. Coleman and Hair, development is being done under the direction of E. M. Hardy.

Salt Lake City.—In a decision handed down by Federal Judge Tillman D. Johnson on December 16, the Utah-Apex Mining Co. was awarded \$1,154,928.98 against the Utah Consolidated Mining Co. for ore extracted from property which had been decreed by the Court as belonging to the Utah-Apex company. Proceedings in execution were stayed for a period of 30 days to give each party time to file notice of appeal, if either so desired. In his previous decision, Judge Johnson held that if the rules laid down by the court to govern the method of arriving at an accounting were closely followed, the figures reached should agree. However, when the revised figures were presented to the court, the Utah-Apex held the amount to be \$1,171,000 and the Utah Consolidated contended that it should have been \$1,070,000, or about \$100,000 less.

TEXAS

El Paso.—It is planned by the American Smelting & Refining Co. to establish here a large metallurgical experimental plant for the testing of ores. The ore for this plant will come chiefly from mines in Mexico, it is stated.

BRITISH COLUMBIA

Barkerville.—In the case of the Mines Operating Co. v. the Lightning Creek Gold Mining Co., Justice Clement has appointed H. W. Dyson, manager for the Yorkshire & Canadian Trust Co., receiver for the plaintiff and other debenture holders. This probably is the last chapter in some unsavory stock-jobbing, in which C. H. Unverzagt used the Wingdam mine, between here and Quesnel, as a means for raising capital in the United States, despite the fact that Justice Morrison had issued an injunction prohibiting the sale of any of the company's assets. Unverzagt used the curious method of selling gold content in certain areas of the property, averring that it would give a return of 10% per month on the investment.—A. Sanders has suspended work on his lode-gold prospect at Proserpine mountain until next spring.—A. E. Platt, the discoverer of the alluvial gold deposit on a plateau, 500 ft. above Cedar creek, Quesnel lake, is making arrangements to work the property on a large scale next spring. It will require 20 miles of flume to bring water to the property.

Nelson.—R. A. Grimes, president and managing director for the Slocan Silver Mines, Ltd., states that recent development at the company's McAllister mine has demonstrated the existence of one and a half million ounces of silver in the mine. The ore averages 33 oz. silver per ton and about

5% lead. The bottom level has been driven for 600 ft. on the ore-shoot, and the face of the level is still in ore. Another ore-shoot has been cut 400 ft. south of the main ore-body. This shoot has been drifted on for 50 ft., and averages 18 oz. silver per ton. Arrangements are under way for the leasing of a flotation plant at a nearby property, and, in the event of their being successful, a tramway will be built from the mine to the plant. In the meantime, the development of the mine will be continued.—The Roseberry-Surprise Mining Co. has employed 30 extra men at its Bosun mine, at New Denver, and is producing silver-lead and silver-zinc ore, averaging 180 oz. per ton in silver. A considerable tonnage is in the shipping-bins ready to be sent to Trail.

Stewart.—R. L. Clothier has bought a half interest in the Salvator group, up the Marmot river, and will give his attention to the mining of ore from the property this winter. The property is situated on a hill-side, from 800 to 1200 ft. above sea-level, and the ore easily can be rawhided to tide-water, and shipped to Anyox, where favorable arrangements have been made for its smelting, the Granby company requiring silicious ore for fluxing. Two veins are being worked: one is seven feet wide and carries \$8 in gold and the other is 18 in wide and averages \$25 per ton in gold.—The Premier Gold Mining Co. is now making regular bi-weekly shipments of precipitate from its cyanide plant.

Victoria.—W. D. Carter, deputy attorney-general, has announced that criminal prosecution against the Britannia Mining & Smelting Co., its manager, and assistant manager is to be commenced at once, in connection with the loss of life in the recent disaster at Britannia Beach. This, of course, is a natural sequence to the finding of the coroner's jury, and undoubtedly such an inquiry would be courted by the company and its managers. An engineer has been employed by the attorney-general to make a thorough investigation.—British Columbia Alluvials, Ltd., with a capital of £70,000 in £1 shares has been organized in London, for the purpose of purchasing and developing placer mines in the Cariboo district.

MEXICO

Compas.—R. Quiroga and Jesus Lugo have taken up six pertenencias under the name of El Rocío close to the Cobriza mine west of here. They are developing the property.

Durango.—Jose Bovio, well-known Italian mining man of Chihuahua, has again added a number of new prospects to his holdings in the Villa Hidalgo camp near Inde. He has recorded with the mining agent his application for titles to the Cuahatemoc and Aztec mines, both of which are promising. Some new shafts are to be sunk and cross-cuts run on both of these properties.—Francisco Iturriza, Florian Zarandova, and Jose Escamilla, native miners of the Inde district, are developing La Alianza mine at a point known as the Bufo de Inde. The mine adjoins the Gran Lucero and the Amazon, which produce gold, silver, copper, and lead.—George Stinson, representing El Rosario Mining Co., has located some new properties in the Victoria district west of the station of Santiago Papasquiaro. Stinson has been mining in Mexico for the past 30 years and has developed some rich and productive mines. At present he is extracting some high-grade gold-silver ore.

El Tigre.—The north continuation of the Waldorf vein was recently denounced by E. W. Graves, of Douglas, Arizona. Good showings of telluride ore were opened up by Glennon & Carr on the Waldorf, and float carrying free gold has been found. Considerable prospecting is being done to the north of the Waldorf along the El Tigre range.

Moctezuma.—J. V. Fryer has taken a lease on the Cuernavaca property of Smith & Whitehead. This mine is just south of the Rubi mine in the Rosario district just west of the Zarape claim of the Moctezuma Copper Co. A new shaft is being sunk.

Nacozari.—Lance & Selter have patented a large claim near the Tule mine in the Sahuaripa district. A 3-ft. vein of lead ore has been uncovered for some distance along the surface. The ore averages 100 oz. silver per ton. A reverberatory and a cupelling furnace will be installed to smelt the ore.

ONTARIO

Kirkland Lake. The shareholders of the Teck-Hughes on December 7 approved the proposals to increase the capitalization from \$2,500,000 to \$4,000,000 and for the sale of the unissued stock at 15c. per share. The money realized will be applied to the payment of outstanding bonds in the hope of reducing the amount of bonded debt to \$342,000, which it is proposed to pay from earnings. The ore-reserves, it is stated, amounted to between \$500,000 and \$1,000,000.

At the Wright-Hargreaves work is progressing on four levels, the gold content of the ore being highest on the 400-ft. level. About 125 tons of ore averaging \$12 per ton is being milled daily. The shaft is being put down to the 800-ft. level.

The Comfort-Kirkland has cut a number of narrow veins carrying some gold on the 150-ft. level.

Porcupine.—Some peculiar but rich ore is being taken from the lower levels of the Dome Mines, the material having the appearance of pressed mud with no visible evidence of gold. It is stated to yield from \$200 to \$300 per ton. Mining men are puzzled to know its composition. Similar occurrences in some of the gold mines of Western Australia suggest the possibility that this material lies at the apex of a deposit of gold tellurides. This view is supported by the finding of limited quantities of tellurides carrying gold in some of the lower workings.

At the Premier Paymaster a cross-cut at the second level has penetrated a body of quartz porphyry about 98 ft. wide containing considerable sulphides. Channel-samples show an average gold content of \$5 per ton across the entire ore-body.

It is understood that the projected merger of the North Dome and the West Dome Consolidated is now assured. A new company will be found and a certain amount of stock will be issued to each of the merging companies, sufficient being retained in the treasury to finance development.

The Hollinger Consolidated has established a new high record by the treatment of approximately 4700 tons of ore in 24 hours. This by no means represents the average, but indicates that the average treated during December will be over 4000 tons daily. No official statement as to how the increase was brought about has been issued, but it is understood to be due to finer crushing before the ore was passed through the stamps. The force of the company now numbers about 2200 men.

Should the shareholders of the Porcupine-Vipond-North Thompson, at a meeting to be held December 28, ratify a proposal of the directors to sell 475,000 shares of treasury stock at 15c. per share, it will put the company in a position to finance the sinking of the main shaft from the 600-ft. to the 1000-ft. level, together with some lateral work.

TASMANIA

Hobart.—The Electrolytic Zinc Co. is pushing on rapidly with its program of construction, and it is confidently anticipated that before the end of this year the first big unit of the plant for the production of spelter, using 15,000 hp. of electric current, will be in operation. This will result in an output of about 50 tons of zinc per day. It is officially stated that the company's staff has developed the treatment of Australian zinc-lead-silver ores to a successful economic reality. Tests to decide the best method by which to treat the large deposits of complex ores in Tasmania are still proceeding.

PERSONAL

The Editor invites members of the profession to send particulars of their work, appointments, etc. The information is interesting to our readers.

Norman Stines is in New York.

H. H. Webb has returned to Santa Barbara.

Courtenay De Kalb was at El Paso last week.

W. H. Seamon, Jr., of New York, is at Lakeland, Florida. Edgar Rickard has returned to New York from a visit to Duluth.

Louis W. Whiting, of Mina, Nevada, is at Hyattsville, Maryland.

J. Power Hutchins has been in Morocco recently; he is now in Paris.

A. H. Means, who has been at Pine Knot, California, is at El Paso, Texas.

T. H. Ryan-Jones is with the Dolores Mines Co., at Madera, in Chihuahua, Mexico.

Harry J. Sheafe is examining the Argonaut mine, in Amador county, California.

Ralph H. Jarvis, who has been in the Philippines, has returned to San Francisco.

George H. Garrey, who has been in British Columbia, has returned to Philadelphia.

William Forstner, of San Francisco, has moved to Oak Bar, in Siskiyou, California.

Albert Burch was at Randsburg, California, last week and at Globe, Arizona, this week.

Charles L. Harrington has moved from Grand Junction, Colorado, to Liberty, Missouri.

Ross E. Douglass has moved from Montclair, New Jersey, to Frontera, in Tabasco, Mexico.

Don C. Billick has moved from Alturas, California, to American Flat, Gold Hill, Nevada.

C. B. Lakenan has returned to McGill, Nevada, after spending a week at Salt Lake City.

G. T. Jackson, manager for the Alaska Gastineau Mining Co., at Thane, Alaska, is at Seattle.

E. J. Franklin, mechanical engineer for the Ray Consolidated Copper Co., is at Salt Lake City.

George E. Bent is at South Porcupine for a short time, and will then return to New Preston, Connecticut.

R. B. McGinnis, who has been at Virginia City, Nevada, now has his office in the Mills building, San Francisco.

Walter E. Gaby is visiting Rockport, Texas, but will return to Aire Libre, in Puebla, Mexico, after the holidays.

W. W. Wishon, now of Kingman, Arizona, has been examining the Greenback mine, near Grant's Pass, Oregon.

W. J. McCormick, mine superintendent for the U. S. Graphite Co., at La Colorada, in Sonora, Mexico, is at Los Angeles.

Edwin J. Collins, of Duluth, is engaged in examination work in Cuba and will return home early in January.

H. B. Tooker, traffic manager of the Jackling interests, is at Salt Lake City. He has been spending some weeks in New York.

Clyde Heller, president of the Tonopah Belmont Development Co., reached Philadelphia on his return from Germany on December 18.

Howland Bancroft, who is now at Panama, has been elected a vice-president and director of the Sinclair Panama Oil Corporation.

H. C. George, of the U. S. Bureau of Mines, has returned to San Francisco from an examination of the Eastern and Mid-continental oilfields.

C. E. Chaffin, New York representative of the General Engineering Co., has returned to New York after a six months trip to South America.

George D. Blood, general manager for the Park-Utah Mining Co., has returned to Park City after spending several weeks in southern California.

J. D. Shilling, general superintendent of mines for the Utah Copper Co., spent a few days at Bingham recently. He has returned to National City, California.

H. B. Menardi, recently superintendent for the Nicklas Mining Co., at Hattle Mountain, Nevada, is now with the Consolidated Fuel Co., at Denver, Colorado.

Clarence E. Allen, general manager for the U. S. Smelting Co. at Salt Lake City will retire on January 1. He will be succeeded by D. D. Muir, manager of mines for the same company.

O. P. Riser, formerly superintendent of mills, and H. M. Merry, formerly chief engineer for the Chino Copper Co., Hurley, New Mexico, have opened offices in the Dooley building, at Salt Lake City, as manufacturers' representatives for mining, milling, and industrial equipment and supplies.

Norman Carmichael, who for 15 years has been general manager for the Arizona Copper Co. at Clifton, Arizona, has been retained by the Phelps Dodge Corporation as consulting engineer for the combined properties recently acquired by them in the Clifton-Morenci-Metcalf district, consisting of those formerly operated by the Arizona Copper Co., the Phelps Dodge Corporation, and the Shannon Copper Co. He will move shortly to New York. J. P. Hodgson, the present manager for the Phelps Dodge Corporation at Morenci, will remain in the district as local manager of the consolidated properties.

Obituary

Joseph Warner Edwards died on November 7 at Denver, Colorado. He was born in 1852, at Philadelphia, the son of Edward Bird Edwards and Lydia Ford Edwards. He attended the Philadelphia schools from 1858 to 1865 and completed his academic course in Switzerland and Germany from 1865 to 1870. He was an ardent student of rocks from early boyhood and chose geology and mining as his life-work. He was a special student in geology at the University of Pennsylvania in 1873 and 1874, and was an aide to Persifor Frazer in the second Geological Survey of Pennsylvania, from 1874 to 1876. He completed a scientific course at the Royal Saxon Academy of Mines, at Freiberg, from 1876 to 1879, and at Heidelberg in 1880-'81, taking high honors in geology, mineralogy, and allied subjects. He became a member of the American Institute of Mining Engineers in 1876, and was an active member in the early formative days of the Institute. He was also a member of the Academy of Natural Sciences of Philadelphia, the Engineers Club of Philadelphia, the American Association for the Advancement of Science, the Mineralogical Society of America, the Colorado Scientific Society, the National Geographic Society, the Franklin Institute, and others, being always ready to join any group of men in the advancement of scientific research or investigation. For forty years his professional career was woven into the pioneer mining history of Colorado and the West. He was a man of high culture, keen analytical mind, and gracious personality. His fine attainments as an accomplished and upright scientist, his genial character, and his loyal friendship are a heritage and an influence that will live long in the memory of his many friends and associates. He belongs to that early group of scientists whose aspirations and labors have done so much to formulate and advance the practice of the profession of mining engineering and to maintain its high ethical standards.—W. D.

Stephen Donaldson, mine captain at the Kirkland Lake mine, was killed in a blasting accident in the mine on December 12. He was 34 years of age, and leaves a widow and three children.

EASTERN METAL MARKET

(By wire from New York)

December 19—Copper is quiet and stronger. Lead is quiet and steady. Zinc is quiet and higher.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 40.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

THE BUDGET

The 'Commercial & Financial Chronicle', commenting on the national budget, says:

"Heretofore, according to Director Dawes, the business administration of our Government has 'labored' (the word is well chosen, and the laboring has been unconsciously shared by the people who bore the burden) under difficulties like those of a private corporation which he imagines for purposes of illustration. This imagined corporation had a president who gave no attention to its ordinary routine, avoiding all responsibility for the proper conduct of its affairs and neither assumed nor delegated active control. Not to be outdone, the administrative vice-presidents were allowed to run their several departments 'without any enforced contact in the discussion of routine business matters of the corporation and as if each separate department was an independent authority in all matters of routine business'. Third, because of the situation outlined in points 1 and 2, 'the several departments operated with almost an entire lack of co-ordination'. No unified system for buying needed material, or selling any surplus existed; a department requiring material never looked or thought of looking to see whether there might be an available surplus in possession of another, but went out into the open market.

"Mr. Dawes adds eight more 'difficulties', which must be condensed for the sake of space. The corporation had not the safety check of being operated for profit, and its funds were obtained by 'a levy upon stockholders per a Congressional appropriation collected through taxes'. There was never a balance-sheet, or an inventory of material and supplies, or a statement of current assets, or even a known way of getting any. When each department was notified of the credit allotted to it, the same absence of definiteness caused outlays to overrun the credit and produce deficits to be afterward taken care of.

"Naturally, the 'corporation' never reconsidered any unwise project taken up by any department; each department felt custom-bound to spend all it could get and incur obligations for something more, and this feeling 'of independence of an executive control, owing to its complete lack of exercise', became so firmly embedded in the minds and the affections of the department heads that conferences looking toward correction of evils growing out of the lack of co-ordination were apparently avoided, lest out of that contact information should develop which might stimulate the head of the corporation to an invasion of the independent control of the departments.

"The administrative department heads were chosen as a rule, with less reference to their business qualifications than to their qualifications as advisers to the president of the corporation along other lines than routine business'. Their tenure was often less than four years, so that they had not time to learn and they never felt responsibility. The subordinate members of departmental organizations 'were encouraged to state the needs of their particular subdivision of their department directly to the agency of the corporation (Congress), which made the desired levy on the stockholders (the public). Finally, the natural tendency in making schedules of expenditure was to consider their relation to popular approval, whether right or wrong', thus often putting a premium on expenditure instead of on saving."

MONEY AND EXCHANGE

Foreign quotations on December 20 are as follows:

Sterling, dollars:	Cable	4.22
	Demand	4.22 1/2
Franc, cents:	Cable	8.18
	Demand	8.20
Lira, cents:	Demand	4.62
Mark, cent:		6.61

Eastern Metal Market

New York, December 14.

Continued strength features nearly all the markets—strength in prices as well as in demand.

The demand for copper continues active and the lower prices are disappearing.

Tin has advanced sharply, due principally to the spectacular rise in exchange on London and to a higher market there.

The lead market is featured by steady buying at firm prices.

Demand for zinc is still light for early delivery, but prices have not receded except in so far as the new freight differential has affected them.

Antimony is quiet and unchanged.

IRON AND STEEL

In both pig-iron and finished-steel markets the near approach of the year-end is evident in two respects. Producers have been more disposed to make concessions to improve their cash position and consumers have limited their buying so that inventory might be brought down to a low point. These influences have created fresh uncertainties as to the prices at which the larger business looked for in the new year will be done, says 'The Iron Age'.

The belief is widespread in the trade that reductions in freight-rates will come early in the new year and that the decision by the Commerce Commission to restore the higher iron-ore rates on January 1 does not mean opposition to a reasonable reduction.

November steel-ingot production showed a slight gain and 20,000,000 tons may be the 1921 total, compared with nearly 41,000,000 tons in 1920.

COPPER

A rather unexpected development is the large demand for early shipment, consumers' needs being evidently heavier than was looked for. Inquiry and business for first quarter continue brisk for domestic consumption, and foreign demand has not abated. The price tendency is firmer, but continues to vary with the ideas of the seller. The chief development is the gradual disappearance of the minimum level for early delivery of 13.50c., refinery or New York, and 13.75c., delivered. Not much more metal can be bought at this price. For January and first quarter 13.75c., refinery, or 14c., delivered, is the minimum. The market is tending toward a 14c., delivered basis. In November deliveries into consumption were probably larger than in any month this year and it is acknowledged that stocks are smaller by a liberal margin.

TIN

As to sales the week has generally been quiet. A moderate business, light in volume, has been done and some fairly good orders have been placed, but there has been nothing like the heavy buying of last week and three weeks ago. The feature is the brisk rise in the pound sterling, which has affected the value of tin here and in London. Spot Straits tin, New York, yesterday was quoted at 32.75c. against 33.50c. on Monday and 31.75c. a week ago. There was a reaction in exchange yesterday from Monday. In London prices yesterday were about £2 per ton higher than a week ago at £169 15s. for spot standard, £171 10s. for future standard, and £170 7s. 6d. for spot Straits. The rapid advance late last week and Monday in exchange put a decided damper on buying. The course of the market the rest of the month is expected to develop, in the opinion of a large importer, a shortage with a consequent premium on spot tin, should any demand develop. Some think December deliveries will be large and stocks small on January 1 because

consumers have been heavy buyers recently, there being probably enough tin on the way to meet spot and nearby needs. Arrivals thus far this month have been 1695 tons with 1740 tons reported afloat.

LEAD

Demand continues steady and prices are firm. There is no reason for any spurt in this market as consumption and production are quite evenly balanced. The leading interest continues to quote 4.70c., New York and St. Louis, at which it is still taking business. Independent producers are asking 4.75c., New York, and 4.40c., St. Louis. The London market is higher, and the rise in exchange has also affected prices so that the American equivalent is about 4.85c. per pound.

ZINC

The market continues quiet and featureless. There is a light demand for early shipment to fill hand-to-mouth needs of some consumers. Inquiry for first quarter is more active. The new freight-rate on prime Western from St. Louis to Eastern points went into effect on December 12 and is now 35c. per 100 lb. instead of 50c. This therefore makes a spread of 35 points between St. Louis and New York instead of 50 points. Prime Western for early delivery is quoted at 4.85c., St. Louis, or 5.20c., New York, with first quarter at five points each month above this level. For first quarter as a whole the quotation is 4.95 to 5c., St. Louis.

ANTIMONY

Conditions are without change. Wholesale lots for early delivery are quoted at 4.50c. per pound, New York, duty paid, with prompt metal at 4.55 cents.

ALUMINUM

Virgin metal, 98 to 99% pure, in wholesale lots for early delivery, is quoted by the leading interest at 19c. per pound f.o.b. plant. The foreign metal of the same grade is quoted by importers at 17 to 18c. per pound, New York, duty paid.

ORES

Tungsten: The market continues without feature. Prices are nominal at \$2 per unit and upward, depending on the grade of ore, the quantity, and delivery.

Molybdenum: Quotations continue nominal at 45 to 50c. per pound of MoS₂ in regular concentrates.

Manganese: The absence of interest in the market is pronounced and quotations are nominal at 20c. per unit, Atlantic seaboard.

Chrome: Large supplies still hang over the market and quotations are nominal at \$20 to \$28 per net ton, c.l.f. Atlantic ports, depending on grade and other circumstances.

FERRO-ALLOYS

Ferro-manganese: The fairly large inquiries before the market a week ago have not been absorbed. Quotations are unchanged at a basis of \$58.35 for both British and American alloy, excepting that sold by the Steel Corporation at \$60, Pittsburgh. A higher price for British is declared possible if exchange continues to advance.

Spiegeleisen: Sales of a few carloads are reported at \$26, furnace, for the 20% grade, otherwise the market is quiet.

Ferro-tungsten: Prices continue nominal at 40 to 45c. per pound of contained tungsten for the domestic alloy with 50c. asked for the imported at the seaboard.

Ferro-silicon: There is no demand for 50% ferro-silicon and the market is nominal at \$60, delivered. The price of the leading American maker is \$85.

Ferro-chromium: Standard American alloy, 60 to 70% chromium and 4 to 8% carbon is quoted at a minimum of 14c. per pound delivered. Imported alloy is available as low as 11 cents.

Belt-killing' Work!

-but TEST SPECIAL RUBBER BELTING endured it

AFTER numerous belting troubles, the Tacony Steel Company of Philadelphia finally selected Test Special Rubber Belting for this belt-devouring drive—a hot saw cutting nickel chrome steel of great density and toughness.

—other belts lasted one month
—Test Special Rubber Belting showed
an average life of three months

The conditions speak for themselves—a belt-traveling over small pulleys at 5654 feet per minute—a sudden belt-racking strain when the saw bites into the steel—a shower of sparks and steel particles—BELT KILLING WORK. But Test Special proved its worth. And—consider this—it cost less than the other kind.

A sample of Test Special Belting with
copy of "Belt Engineering" sent on request

Fifty Years of Progress in a Great Industry

ALLIS-CHALMERS MANUFACTURING COMPANY and its predecessors have been identified with the development of mechanical equipment used in connection with mining and metallurgical operations during the past fifty years.

This period covers the development of the precious metal mining industry in the United States, as well as the metallurgical processes connected therewith from its infancy. Prior to the discovery of gold in California, in 1849, very little gold, silver, copper, zinc or lead was produced in the United States.

There was some gold mining—both placer and quartz—in Georgia and the Carolinas and lead was mined in Illinois, but the methods employed in the mining and reduction of ore were based on European practice and compared with present day methods were crude and costly.

The discovery of gold in California stimulated prospecting for this metal throughout the mountain regions of the west and incidentally led to the discovery of large and valuable deposits of other precious metal-bearing ores, such as the Comstock gold-silver mines at Virginia City, Nevada, the lead-silver mines at Leadville, Colo., and many others. The discovery of these large bodies of complex ores created a necessity for new metallurgical processes and improved methods of treatment.

The inventive genius of American metallurgists and chemists asserted itself and an era of improvement in old methods and discovery and development of new processes followed rapidly until today American mining and metallurgical practice is recognized as pre-eminent the world over.

Concurrent with the discovery and development of new metallurgical processes and methods for the treatment of ores American Mechanical Engineers and Manufacturers invented and improved the mechanical apparatus and equipment necessary to make such new processes and methods mechanically and commercially operative.

Present day mechanical equipment used in connection with mining and metallurgical operations has reached a high state of perfection in this country. ALLIS-CHALMERS MANUFACTURING COMPANY and its predecessors, Fraser & Chalmers, E. P. Allis Company and Gates Iron Works, have unquestionably been the largest contributors to the development and improvement of this class of machinery. "ALLIS-CHALMERS" machinery is recognized as Standard everywhere and is to be found in every prominent mining district in the world.

No other manufacturer is in position to offer on such a complete line of mining and metallurgical machinery, including Power and Electrical equipment, designed and built under the direction of one organization, as Allis-Chalmers Manufacturing Company. Its products include a complete line of hoists, pumps and compressors for mines, ore crushers and fine grinding equipment, including ball and rod mills, concentration, cyanidation and chlorination machinery, roasting, smelting and converting equipment.

RECORDS AND AVERAGES

At the Hetch Hetchy Water Supply Tunnels

No. 248 "LEYNER-INGERSOLL DRIFTER"

WE are proud of the exceptional advance of 776' of 11' 3" section tunnel in 93 shifts at the Priest Heading—but we are prouder of the average of 6.1' per shift covering all of the Headings.

This excellent average demonstrates the dependability as well as the speed of the No. 248 Leyner-Ingersoll Drifters which were used exclusively in the headings listed below.

We will allow the facts to speak for themselves.

86,400,000 Gallons Every 24 Hours

is the capacity of this standard Cameron Centrifugal Pump which has a discharge opening of 42-inch diameter.

If you want a pump to handle a large quantity of water all the time, or one for pumping only a small number of gallons during certain hours of the day, there is one particular Cameron best suited to your needs.

Regardless of its size, every Cameron Pump is a product of the same careful and progressive methods of pump building which have made these pumps standard equipment in almost every industry for more than sixty years.

Every pump is guaranteed to meet the exact conditions for which it was sold. A thorough shop test and final inspection before shipment for hydraulic conditions, efficiency and power consumption at all capacities is your protection.

For dependable pump performance, specify Cameron.

LEVIATHAN Conveyor Belts

—tough all the way through!

When you consider buying a conveyor belt, make sure it possesses three qualities:

1. Toughness
2. Toughness
3. Toughness

If it's tough on *the conveying surface*, tough in the *middle* and tough on the *driving surface*, it's a good conveyor, no matter who makes it or what it's made of.

Toughness that goes *all the way through* is the only kind of toughness worth paying money for, because when the surface wears off you've got a new tough surface underneath.

LEVIATHAN is tough—*all the way through*.

It would be tough even without any impregnating material, because it is *Tensated*.

Tensation is an exclusive process that makes LEVIATHAN

the *densest* belt known. This means that abrasive dust and particles have the hardest kind of time working into the fibres.

Then add the impregnating material.

This material is the result of hundreds of experiments in our own chemical laboratory with special testing apparatus of our own design. It won't crack in cold weather. It stays hard in heat. It is waterproof. It resists acids and steam. When forced into the fibres of LEVIATHAN, it forms an almost impregnable shield against abrasion.

LEVIATHAN is the *toughest* belt made.

You be the judge—try it and compare it with the best conveyors you have ever used.

We'll be glad to send you our booklet on "Conveyor Problems and Their Solution."

Traylor Equipment Is Feature Equipment

Traylor "Bulldog" Jaw Crusher Features Have Lessened Operating Cost

THE terrific strain of breaking tough rock and ore demands a jaw crusher that will stand up to its work day after day, give capacity, show low maintenance expense and above all—**keep running.**

Traylor engineers developed such a crusher in the "Bulldog" jaw. They worked out features which cut down friction, with no loss in strength. They lessened power consumption because of decreased weight. They gained capacity because of smooth-working moving parts made to do their full proportion of useful work by the unyielding frame.

They now stand back of the Traylor "Bulldog" Jaw Crusher and vouch for it as the highest development in jaw crusher construction.

Traylor
"Bulldog"
Jaw Crusher

Why So Much Confidence In Traylor "Bulldog" Jaw Crushers?

Because of the frictionless toggle-system, with bearings that roll instead of grind and which do not get out of alignment.

Because of the pitman—made up of wrought-steel rods of known, tested strength, and carrying far less weight than any known previous type.

Because of the unyielding frame with its steel reinforcing bands at the base and around the jaw opening—because of the way in which the frame is held under constant compressive strain by the unyielding steel bands.

Another reason why Giants produce "Dependable power at less cost per hour"

IN many oil engines combustion is effected in the *cylinder*. This causes difficulty in securing efficient lubrication, causes troublesome carbon formations and increases power costs because of incomplete combustion.

Combustion in Giant Semi-Diesel Oil Engines is effected in the *cylinder head*. This facilitates lubrication, minimizes carbon formation and confines it to an area where it is readily and inexpensively removed, insures complete combustion, and thus provides unequalled fuel economy, lowest upkeep costs and 24-hour-a-day dependability.

Not alone in this one feature do Giants excel—they possess the all-important *cross-head construction* which feature prolongs the working life of an engine, prevents undue wearing of cylinder walls and pistons, and insures constant alignment and long life of the cylinder and reciprocating parts.

You'll find other interesting features described in Bulletin 389. Ask for it through the nearest Branch. Make it your first step towards obtaining *dependable power from low-cost fuel!*

AERO BRAND CYANIDE

AMERICAN CYANAMID COMPANY
 511 FIFTH AVENUE,
 NEW YORK

T. A. RICKARD, Editor

STATISTICIANS aver that warehouse stocks of automobile tires now total 3,500,000 as against 10,000,000 a year ago. Among others who are pleased with this information are the producers of zinc; renewed activity on the part of tire manufacturers means increased demand for zinc oxide, for at the present time half of the zinc output of the country is being absorbed by the tire fabricators, as compared with about a quarter in former years. Improvement has been reflected in the price for the metal and production has increased materially; rumors are heard that the Butte & Superior company is to resume operations at once.

DISCUSSION this week starts with an informing letter from Mr. Lucien Eaton, who gives further data on the use of scrapers underground, in sequel to his valuable article on that subject. Three contributors supplement and correct our recent editorial on the newly prominent mining district of Royston, or San Antonio, in Nevada. We thank them for the information they give. Mr. C. Flury writes from Korea on the regeneration of cyanide, a highly technical matter to which reference was made in an earlier article by Mr. Algernon Del Mar. The controversy between Mr. Leon Perret and sundry American mining engineers, on the methods of placer mining in use in Russia, is clarified somewhat by a letter from Mr. W. E. Thorne, who has been on the ground and is familiar with the facts. Our friend Mr. Thomas T. Read discusses the letter from Mr. S. H. Dolbear on 'Wetting and Amalgamation', appearing in our issue of November 12. His own earlier researches in amalgamation enable him to suggest several interesting likenesses and differences in the two physical processes. The last letter under 'Discussion' is from Mr. Warren D. Smith, who writes from Manila on the proposed revision of the mining law. He draws upon his knowledge of conditions in the Philippines and emphasizes the fact that there, as in the United States, the development of mineral resources is checked by the passing of the land into the hands of those unwilling or unable to explore or exploit.

THE collapse of Silver Hills as a mining enterprise is chiefly of local interest, but it has phases that are worthy of comment. The mine is in Nevada, it was commended by a reputable engineer, and looked promising. Unfortunately what good features it had were exagger-

ated for the purpose of boosting the shares on the San Francisco Stock Exchange, which has an unsavory name. The shares rose from 8 cents to 66 cents, largely, it is alleged by the Commissioner of Corporations, because of cross-sales, whereby a fictitious price was created. The broker held responsible for this performance, Mr. Don C. Aldridge, has announced his intention of bringing suit for damages against the Commissioner. We hope he will, for the ventilation of the matter in court would test the power given to the Commissioner of Corporations by the law designed to check the queer practices of the local exchange. Unfortunately at this juncture it is announced that Mr. E. C. Bellows, the Commissioner, is to resign from office to accept a highly remunerative appointment as president of an important financial institution. We hope he may receive at least half of the gorgeous salary mentioned in the daily press; but, even if it fall far short of that, the transfer of his energies from public to private business exemplifies again the fact that an honorable tenure of office under the State is used by many, properly enough, as a means of personal preferment, and that under our system of political appointments it is impossible for the State to retain a good man for long. Our own impression is that Mr. Bellows has discharged the duties of Commissioner of Corporations with fairness and sincerity for the benefit of legitimate industry in California; so we wish him well in his new departure. As for Mr. Aldridge, this is not the first mining-share fiasco in which he has figured, and we feel strongly that it will be well for mining if less delving into pockets is done on Bush street and more digging into the ground at the mines. Mr. Aldridge received on his own account one share for every share that he sold to the public; he is cruel to some of the victims of his own stock-jobbing activities when he asserts that "the cupidity of some of the speculators got the best of them and caused them to buy more than they could pay for, the brokers carrying the stock for them on loan accounts". We suppose that this result was in accord with the purpose of a share-boosting campaign. After the collapse, it appears that Mr. Aldridge proposed to increase the capital of the company by 500,000 shares, and to take an option on these shares at 8 cents apiece, with a view to financing a new start on fresh property in Arizona. He says: "I had hoped that I would be able to make a second profit for the shareholders, but I do not propose to be criticized by the

Commissioner of Corporations". Whether the shareholders desire a "second profit", just like the first one, we do not know, but it seems to us that the Commissioner is warranted in criticizing Mr. Aldridge and his kind.

UNBIASED testimony is always valuable and often interesting. Mr. Fernando Benitez in his concluding article in this issue, on the operations at Catemu, Chile, deals at length with labor conditions in that country. He pays a well-deserved tribute to the sterling qualities of the Chilean, who on the average is a hard worker, a mechanical genius, and an obedient and law-abiding employee; to his friend he is generous to a fault; to those who would drive him at his task he is soon dissatisfied and sullen, sometimes openly aggressive. Mr. Benitez draws attention to the conditions under which the average Chilean laborer lives, likening his habitation to a pig-sty, in which sanitation is conspicuous by its absence. It is therefore with a great deal of gratification that we note the tribute that he pays to the large American corporations for the success that has been achieved by them in welfare work in Chile. We agree that Chileans appreciate the advantages and improvements that are evident at an industrial centre such as Chuquicamata; and it is hoped, as Mr. Benitez says, that other mining and industrial concerns will copy the splendid lead that has been given by American operators. A frank statement such as this has been needed for some time, if only to counteract the insidious propaganda of misrepresentation, in regard to the attitude of American corporations toward Chilean employees, that appears to pass unchallenged. As an example of this we have before us a book published recently in Santiago entitled 'Chuquicamata, su Grandeza y sus Dolores' ('Chuquicamata, its Glory and its Grievs'). The cover, in brilliant colors, depicts a small boat-load of cowering and frightened Chileans, one of whom is preparing to jump overboard to escape the horrors that appear to be imminent. Standing above these cringing unfortunates towers what our South American friends would term a Norte-Americano, who is identified by a waist-belt ornamented with the Stars and Stripes. This individual, of giant stature, bloodthirsty appearance, and menacing attitude, is flourishing an oar toward the group of terrified Chileans who are huddled, helpless and dismayed, at the other end of the boat. It is lamentable that such an absurdity as this should receive the sanction of publication by the Chilean authorities. The implications insinuated by the title and the illustration on the front page, as well as the derogatory reference to American enterprise in Chile in the book itself, are so stupid and so absurd as to appear ludicrous to anyone who knows Chile and who has taken the trouble to learn the facts of the case. The misunderstandings that arise and the trouble that is fomented by the publication of such despicable misinterpretations of conditions can only be removed by permitting the fullest publicity; and this attitude, we are glad to say, has characterized the policy of the Chile Exploration Company since the inception of its operations.

Anaconda Copper and American Brass

The absorption of the American Brass Company by the Anaconda Copper company seems to be assured, although the final decision rests with the stockholders of the former company, who under the terms of the present offer may exchange their stock on the basis of \$150 cash and three shares of Anaconda for each share of American Brass, provided 51% of the stock outstanding be offered. Anaconda's shares are selling at about \$50, thereby placing a valuation of \$45,000,000 on the capital stock of the other company, shares in which have recently advanced to \$300 from \$165, doubtless in anticipation of the proposed merger. In 1918 the American Brass Company fabricated 600,000,000 pounds of metal from its five extensive plants; it is now the largest single consumer of copper in the United States, and in recent years has done about 40% of the brass manufacturing of the country. In normal times the Anaconda company produces from its mines at Butte less than 300,000,000 pounds of copper per year; so it is apparent that the merger, if consummated, will provide amply for the disposal of whatever copper is left after the demands of the company's rod- and wire-mills at Great Falls are satisfied. Account must necessarily be taken of the large production of zinc from the mines at Butte, and of the copper that will be produced by the subsidiary companies in South America. The large steel corporations control companies that produce the raw materials, including both ore and fuel; companies that smelt the ore, others that convert the iron into steel, others that roll the ingots and fabricate the shapes; and finally those that distribute the finished product and sell it to the consumer. In this unification of control is supposed to lie much of their strength, and it seems evident that the Anaconda company has in view a similar organization of its operations. One of the peculiar conditions that has obtained in the copper industry has been the wide 'spread' between the market price of refined copper and the cost to the user of manufactured copper products. Numerous explanations for this have been advanced, but no entirely convincing figures have been offered to show that somewhere between the producer and the consumer there has not been unwarranted profit, or unnecessary waste in methods of manufacturing and marketing. The inevitable result was restriction in the use of copper products. The interest of the Anaconda company obviously lies more in stimulating the consumption of copper in order to increase the demand for raw material and to afford an outlet for the product of its mines, than in making profits on manufactured articles. It seems reasonable that co-ordinated administration of all branches of the industry will permit more efficient manufacturing and selling by the Anaconda company, to the end that the consumer as well as the producer may profit. The result should be that other manufacturers, to survive, must conduct their business more economically, and in the end not only the copper mines but the zinc mines throughout the country will share the benefit.

America's Oil Supply

A plea for the unification of American oil enterprises that are operating in foreign countries is made by Mr. L. G. Huntley, of Messrs. Johnson, Huntley & Somers of Pittsburgh and Dallas, who contends that the random operations of such concerns are seriously handicapped by many disadvantages. These include limited capital; insufficient and inexperienced organization for foreign work; secrecy, as a result of competition; local jealousy of foreign governments, encouraged by the fact that rival interests are often competing for concessions at the same time; lack of consular and diplomatic assistance; difficulty in obtaining protection from the operation of unfavorable and retroactive laws, passed after development has reached a favorable stage, which take the form of stringent labor regulations, unreasonable export and production taxes, and arbitrary royalty charges; lack of military and civil protection in some countries; insufficient knowledge of local laws and customs, and of title requirements; absence of financial connection with established banks in foreign countries; and departmental indifference or active antagonism at Washington.

It is maintained that in foreign fields the duties of acquiring land, of developing production, of building roads, pipe-lines, terminals, railways, and floating equipment may devolve on the foreign manager, who, in addition, is required to attend to a considerable amount of political and legal work. This is not conducive to efficient operation. Furthermore, the capital needed is invariably considerable, and only a few of the stronger groups in the American oil industry can take the risk that is involved in bearing the preliminary expense. Thus it is that the smaller operators become discouraged before achieving their purpose; or, when drilling operations have been successful, they may sell to stronger groups, not always at a profit. Few of the companies operating in the domestic oil-fields have had sufficient experience in foreign countries to have built up a personnel that is efficient for the work; the majority of their employees are unwilling to go abroad or incapable of taking charge of operations away from home, although these may be similar, technically considered, to those in which they may have had much experience in the United States. This is not surprising, for ignorance of a foreign language, of local customs, of climatic conditions, and of the labor that is available in foreign countries constitute obstacles that few men of middle age care to take the trouble to overcome. We agree with the contention that a certain virile type of mentality and outlook is necessary for successful work abroad, coupled with a breadth of view and an absence of insularity. The capabilities of the engineer engaged must include resourcefulness and an ability to use materials and to adopt methods that are available, regardless of past experience, rather than to wait for the arrival of shipments that may be delayed and for skilled labor from the United States. Many men are so accustomed to calling up a supply-house on the telephone, and requisitioning

material in routine manner, that they are helpless when such facilities are unavailable. If an employee be discharged from the ranks of an oil company operating in the United States, he can be replaced usually almost immediately by another who is equally as efficient. When a similar need for dismissal occurs in a foreign country it may be weeks or months before the employee can be replaced; meanwhile important work is delayed, unless the manager be a resourceful man.

Being accustomed to playing a lone hand in the domestic oil fields, says Mr. Huntley, some companies have adopted similar methods abroad; but the average Spanish-American is disposed to be suspicious of foreigners; therefore such secrecy encourages conclusions that are unwarranted. Competing interests, particularly those of nationals other than North Americans, as they call us in South America, sometimes take advantage of this suspicion to inculcate mistaken ideas in the minds of the natives, to the embarrassment of American companies, each of which may be instigating political intrigues in order to get concessions. Inter-company friction is detrimental to such enterprises. It is maintained that Americans have learned to avoid their consulates and legations when they need assistance; an instance is quoted in which the U. S. Minister to a foreign country failed to lend such assistance because he was backing the activities of several irresponsible promoters who were preying on the resources of their more solid competitor by attacking his title. This, of course, is deplorable. Small companies apparently cannot claim assistance from governmental sources without the suspicion that favors are being sought and discrimination invited.

Ignorance of local laws and customs also constitutes a factor that is unfavorable to efficient and successful operations abroad. Small companies that desire to enter the foreign field are handicapped by a lack of knowledge concerning the conditions under which oil-lands may be acquired or leased; they may accept a defective title to concessions or to land that is owned privately. Unavoidable duplication of such grants often occurs, to the enrichment of a type of lawyer that is only too common. It is maintained that the title to oil-lands in all the countries of Central and South America is invariably unsound, and that the defects usually are not discovered until the land has become valuable as the result of exploitation. The small development company may find that it has spent a great deal of money in exploring land to which it has no good title; or at least upon which there is enough defect to throw the whole affair into the courts for years, until a substantial blackmail has been collected, either by the parties attacking the title, or by the courts, or by both. A large corporation would be relatively immune from such annoyances.

Excessive taxation on the part of foreign governments has been the ruin of many American enterprises abroad. Mr. Huntley emphasizes the fact that politicians are notoriously shortsighted and are usually governed by selfish aims. We are inclined to agree that the tropical variety is sometimes particularly unscrupulous; in the

absence of an intelligent public opinion their actions often take the form of harrying foreign corporations for monetary gain. Industries that were backed by American capital have been started at various times in such countries; some had reached, not without an unusual display of courage and skill and initiative, the stage when a reasonable profit seemed assured; then came excessive taxation and governmental legislation of various kinds, which was designed to squeeze all available profits for the pecuniary benefit of the clique that controlled the government at the time. It is maintained, strange as it may seem, that the adoption of such a policy of ignorance and shortsightedness is on the increase. The result of recent tax decrees in Mexico is such that it will be impossible to maintain further development work in the less prolific oil-fields; the cost of production and the high rate of amortization of pipe-lines and other equipment will make such development economically impracticable.

Mr. Huntley affirms, and with logic, that although we produce sufficient oil within the United States at the present time for our own needs, we must look ahead, so that when our present resources are exhausted or depleted we may still be able to maintain a position of security in regard to future supplies from those parts of the world in which oil-lands have been developed in consequence of the initiative and capital of American companies. It is proposed that a syndicate or corporation be formed, comprising the principal oil groups, most of whom are engaged already in preliminary operations in foreign fields, to meet every requirement of the business in those countries in which it decides to operate. The syndicate would absorb the foreign operations of its members, issuing stock or shares to each on the basis of the value of holdings, as decided by a committee of appraisers. It is mentioned, however, that the principal independent groups in the American oil industry have been built up and are controlled by men of unusual initiative, and these possibly would object to a co-operation that might lead to the submerging of individual identity, foresight, and energy. An alternative plan is therefore proposed by which the syndicate would act merely in a financial and protective capacity, for which it would be entitled to an option on a portion of the oil produced. In such case the syndicate might operate its own tankers, and pro-rate the oil among the refineries of its members. It is claimed that the formation of such a syndicate would encourage individual initiative by providing capital at reasonable terms and by furnishing transportation, at a fair price, for oil produced by American companies operating in foreign countries; it would lessen competitive jealousy and would strengthen the influence of American oil companies in foreign capitals; it would furnish readily accessible information on laws, customs, operating conditions, costs, and general data of interest to companies operating abroad; it would ensure a measure of protection against confiscatory decrees and unreasonable taxation, and in general would ensure a large measure of political protection; and, finally, it would stimulate co-operation at Washington, without which, it

is claimed, American enterprise must abandon, once and for all, any hope of successful operation in foreign fields; for without this it will be the prey of every self-seeking politician in the country in which it is operating. As a trading and manufacturing nation our self-preservation demands that the sources of an essential raw material such as oil be controlled adequately, especially when developed by American energy and American capital.

Platinum

In our last issue we made some comment on the purported discovery of platinum ore near Winnemucca, Nevada. One chemist found platinum in numerous samples, whereas others found none in samples from the same source. The first man insisted that the metal was present, and inferred that the other analysts did not know enough to detect it. Without implying any reflection upon the first chemist, it may be said that a few years ago, when the high price of platinum stimulated prospecting for it, sundry ignorant or dishonest assayers in the Western States made a practice of reporting platinum in rocks that subsequent investigation proved to be barren, for practical purposes at least. The revenue from making assays at \$2 each apparently induced strenuous effort to 'detect' the metal and thereby encourage dozens of new prospectors to bring hundreds of new samples. Fifty samples per day meant \$100 per day. When the results were not confirmed by assayers of wide experience and established reputation, the man who had made the encouraging assay resorted to the claim that the particular kind of platinum present in the ore could be detected only by a 'special' method, the details of which, for obvious reasons, he did not care to disclose. The implication was that the 'big city' chemist did not know his business. Unfortunately the text-books on methods of ore analysis did not detail any complete and specific method for making assays for platinum, and this fact lent color to the claims of the possessors of alleged secret methods. The established chemists knew exactly what they were doing and were sure of their ground, but this absence of clear instructions and procedure, authenticated by the subtle power of publication in print, enabled the unscrupulous assayer to envelop in a cloud of mystery the whole matter of testing ores for platinum. The sufferers were the prospectors, who were led to devote their time to a search that was almost sure to be fruitless and to spend money on assays that were worse than worthless. This was one of the considerations that led to the preparation of Technical Paper 270, by C. W. Davis of the U. S. Bureau of Mines. Besides a quantity of exceedingly interesting information, this pamphlet gives a selected method for making an analysis of a sample of ore, detailing each operation so that any intelligent assayer can do the work. As the author says, the scheme contains nothing new; but it does put the facts in black and white. We venture the opinion that there is much more likelihood of an assayer 'finding' platinum in an ore that contains none than of his failing to find it in an ore that does contain an appreciable quantity.

DISCUSSION

Use of Scrapers Underground

The Editor:

Sir—In your issue of December 3, Mr. C. F. Jackson, in commenting on my recent article on the use of scrapers underground, gave a brief description of the Evans scraper loading system, as used successfully by the Hudson Coal Co., and called attention to Mr. H. D. Kyner's paper on 'Mechanical Methods of Mining Anthracite', presented at the Wilkes-Barre meeting of the American Institute of Mining and Metallurgical Engineers last September. Although I have never seen this system in operation, I have read descriptions of it in the article on loading machines by Mr. A. M. Gow, published in the 'Engineering and Mining Journal', Vol. 109, No. 5, p. 319, and in the catalogue of the Goodman Mfg. Co., as well as in Mr. Kyner's paper. The Evans system is also described by Mr. Ward Royce in an article published in the 'Engineering and Mining Journal' of December 10, 1921. I referred to it in an article in the 'Compressed Air Magazine', published in May 1921.

The equipment used with the Evans system is too heavy to be taken up and down raises, in mines where the ores is mined by top-slicing methods, and it requires a crew of four or five men. On our sub-levels, in order to get the best results, the scrapers must be run by the miners themselves, without outside help, and this limits the crew to two men. By using a snatch-block and roller, as in the Evans system, we could pull a scraper around a right-angle turn, but it would require an extra man at the turn, or at least take away the man who now works in the breast, thereby slowing up the loading operation. It is possible to get around a right angle with the scraper by making two 45° turns close together, but this complicates the timbering. I am at present studying this problem, and hope to work out an arrangement by which the turn can be successfully made without increasing the number of men.

I agree heartily with Mr. Jackson in his regret at the lack of interchange of ideas between coal and metal miners, and have felt for some time that at the sessions of the American Institute the division of the members along these lines is a mistake. After the ore or coal is broken, the business of mining resolves itself very largely into a problem of transportation, the solution of which often determines the success or failure of the enterprise.

Referring again to my article in your issue of November 19, I made the statement, on page 707, that "the main disadvantage is that in drifting no drilling can be done while the scraper is in use". I have since received

a letter from Mr. Charles L. Lawton, general manager for the Quincy Mining Co. at Hancock, Michigan, in which he says: "At no time in our experience with drift scrapers has their use interfered with drilling or blasting. The drilling goes forward the same as though the scraper and incline were not installed or in operation". This is welcome news, and I am glad of the correction. I have never seen drilling done while the scraper was in use in a drift, and have never attempted it.

LUCIEN EATON.

Ishpeming, December 13.

Royston

The Editor:

Sir—The editorial about the new camp of Royston, in your issue of December 10, is interesting and instructive. At one point it seems to carry a great lesson. You say, referring to Charlie Poy, the Chinaman, and his negotiations for the purchase of a quarter interest in the Betts lease: "who went himself to see the ground and to judge of its promise as a mine".

This shows that we Americans have much to learn from the Chinese. Most of us would have hired (what is the proper word: retained or hired?) a mining engineer to look at the lease for us, and have given him \$150 for his unfavorable opinion. I have little doubt that several unfavorable opinions by engineers might have been obtained in Tonopah without even going to the trouble of making an examination.

The cold fact of the matter is that the great majority of mining engineers are absolutely unqualified to determine the value of a prospect. They turn 'em down simply as a matter of principle. It seems to be a source of constant wonder to you that prospectors do not love the engineering profession. The only wonder to me is that the average prospector will allow an engineer to step on his ground.

E. C. WATSON.

Luning, Nevada, December 13.

The Editor:

Sir—The mention of San Antone in your issue of December 10 recalls the fact that it was one of the early centres of prospecting in the State of Nevada. When Governor Blaisdell's exploration party of 1866 was homeward bound we had been fortunate enough to get into touch with Indians, and when in the vicinity of what is now Tonopah our guide for the day told us that "White men were fighting rock", pointing to the north.

A former Indian agent had joined us at Hiko and acted as interpreter. As white men and civilization were just what we wanted above all things by that time, we naturally took the hint and found that at some prior date prospectors had dug holes all over the region and apparently abandoned it. Feeling that we had earned a rest, and that our troubles were over, we made camp. Wandering from pit to pit it struck me as peculiar that while many of them showed ore there was none of it lying around the openings. I finally came across a good-sized dump, much bigger than could have come out of the adjacent hole, and discovered that someone had patiently collected all the visible supply of ore in the neighborhood to enhance the value of his own location in the eyes of a promoter. While engaged in sorting the pile to see how many types the owner thought permissible for a tender-foot, the lone inhabitant turned up, and strenuously, in language impolite, wanted to know why I was monkeying with his property. He learned that his scheme might prove a boomerang as suggesting a want of honesty on his part, and we parted good friends. In later days he probably made a good promoter. The Chinaman is not alone in tricks that are strange!

I do not recall that we had any trouble on the water question. The Indians apparently seldom knew the water-holes more than a day's journey ahead, but as we generally got a new guide daily, they always took us to water. They were inconceivably low in the scale of humanity, many of them clad in nature's scant attire, with lizards and wild vegetables for food, small bows for weapons, and fire a most precious possession. Many had never seen a white man.

R. H. STRETCH.

Seattle, December 12.

The Editor:

Sir—Permit me to correct several minor errors appearing in an editorial 'Royston, or San Antone' in your issue of December 10.

Lodi is to the west of the Ellsworth range. Lone, Berlin, and Union Canyon also were important producers in the early days of mining in the Shoshone and Toyabe ranges. Ophir Canyon is about 35 miles in a straight line and nearly due north from Royston. Both are on the west side of Big Smoky valley. The Murphy mine was the main producer in Ophir canyon, with a mint record of five million dollars in silver, and probably that much more otherwise disposed of. The railroad records at Austin, the terminus of the Nevada Central railroad, show that over sixty million dollars worth of ore and bullion has been shipped by that route from this part of the State, despite the cursory system of prospecting in vogue. As an illustration I can state that I have shipped ore returning 5 to 13 oz. in gold, and silver-lead ore returning 73 oz. silver and 66% lead from several different places within 1½ miles from the old Ophir Canyon mine. All of these places yielded shipping ore at the surface. Recently 200-oz. silver-lead and 258-oz. silver ore has been found to the north and west of the old mine, not more than a mile and a half from it.

While none of these discoveries thus far have developed into a Randsburg, they are that much evidence of outcrops of shipping ore that have been overlooked. The old Ophir Canyon mine was 'worked out' several times, and is now being re-opened by the Ophir-Nevada Company.

Regeneration of Cyanide

The Editor:

Sir—Referring to 'Cyanide Notes', by Algernon Del Mar, in the issue of June 11, and with reference to the statement to the effect that the regeneration of cyanide increases as the precipitation of basic zinc carbonate increases, I think that it would be difficult to precipitate the zinc salt in the presence of soluble lime salts, on account of the affinity of calcium for carbon dioxide. The precipitation of carbonate of lime would occur first, and before zinc cyanide is converted into basic carbonate.

The formation of basic zinc carbonate in the solution must be due to the reaction of soluble carbonate of lime or other substance formed by the action of the air on the alkaline solution. The base of such reaction would be the carbon dioxide. The conversion of zinc cyanide into the basic carbonate would follow the equation:

This equation indicates that for the formation of basic carbonate of zinc ($\text{Zn}(\text{OH}.\text{CO}_2)_2$) an excess of carbonate is necessary, otherwise the ordinary carbonate would be formed:

Theoretically, by an increase of carbonate in the solution, a regeneration of available cyanide would occur. If the carbonates are in excess, basic zinc carbonate is formed; if the carbonates are equal in amount to the zinc cyanide present, zinc carbonate would result. Consequently, an addition of carbonate or bi-carbonate of soda would favor this reaction; in the case of the bi-carbonate, the basic zinc carbonate would result, thus:

In the case of carbonate of soda, the ordinary carbonate would result, thus:

Although theoretically promising, this reaction is impracticable; soluble lime salts cannot effect a regeneration

of cyanide in this way. Actual tests show that by adding bi-carbonate of soda or carbonate of soda to the tailing solution, calcium carbonate precipitates first; the amount of alkali cyanide is not increased; but I found an increase of the alkalinity almost in strict proportion to the carbonate or bi-carbonate added.

I conclude that such regeneration, if it really occurs, has no connection with the formation of basic zinc carbonate; that when soluble lime salts are in excess, the precipitation of basic zinc carbonate is impossible. Consequently I can see no connection between the regeneration of cyanide and an increase of basic zinc carbonate. The addition of carbonate or bi-carbonate to a tailing solution does not affect a regeneration of cyanide.

Russian Placer Mining

The Editor:

Sir—In regard to the Perret-Purington controversy, I hold no brief for either party, but I know some of the facts and believe in fair play.

I arrived on the *Lena* in April 1913. Mr. Perret was then manager. Soon after, I met him and we discussed mining in general, he giving his Ural experience and I mine in the Klondike and Alaska along the same lines. He then informed me that he proposed to install winter-washing, rope-haulage, recovery of timber, with such changes in underground work as would tend to reduce costs.

About July of the same year, Messrs. Purington, Smith, and others came along. In August some arrangement was made for Mr. Smith to act as technical assistant to Mr. Perret, and follow his instructions. This he did for about one year, when Mr. Perret resigned and was succeeded by V. N. Zhurin. Mr. Perret's scheme for changes and improvements being well under way, it was continued, Mr. Smith remaining on as assistant.

Mr. Purington became consulting engineer in 1914, but no change in the working of the property according to the Perret plan was made up to the end of 1917, for I remained to the end of that year, when the Bolsheviks chased me out through Vladivostok. Mr. Purington deserves credit for pressing the Russian management to get Mr. Perret's plans carried out.

There was a mechanical elevator recommended by Mr. Purington on the Tikon mine. That was a failure, but no one seems to care to claim this. In addition to ignorance of the Russian language, Mr. Perret should have added "and character" as the cause of failure in a good many instances. Apropos of his remark as to the 17-in. ft. dredge and its transport, the *Lena* company has many heavy pieces of machinery already there, such as railway locomotives. Climatically Siberia is not different from the Klondike or Alaska; in fact, there is less frost on the Bodaibo river.

The Russian engineer technically is A1. Some lack practice, but this is true of engineers in other countries.

The workmen are good enough when properly directed; one must use some diplomacy to succeed in any foreign country.

W. E. THORNT.

London, November 27.

Wetting and Amalgamation

The Editor:

Sir—Probably it was only coincidence that your editorial on the waste of experience appeared in the issue in which you printed Mr. Mason's letter on wetting in amalgamation. You quote Mr. Carnegie as saying that his organization had wasted a great deal of money because it failed to find out what others had done before research and experimentation were commenced. Mr. Mason describes a series of experiments he performed about 1900, which covered much the same ground as those made by Henry* in 1855. De Sours, Merz and Weith, Schmauss, Knafl, Chester, and Dudley had all published their experiments along this line previous to 1890. In his determination of the solubility of gold in mercury, he had been anticipated by Kasantseff in 1878 and by Dudley in 1889. All the literature bearing on this subject that appeared previously to 1906 was summarized in my paper on amalgamation of gold ores, published in the Transactions of the American Institute of Mining Engineers, Vol. XXXVII, p. 56 (1907). But perhaps Mr. Mason only worked for his own amusement; that would seem a justifiable inference from his not having published his results.

Reverting now to the main subject, it seems to me it cannot be discussed usefully without a more precise statement of the question than is contained in Mr. Dolbear's letter, published in your issue of November 12. When a fragment of gold is brought into contact with mercury, it is most certainly wetted by the mercury in exactly the same way that a mineral particle is wetted by oil when brought into contact with it. It is practically certain that a mercury film would be adsorbed on the gold surface in exactly the same way that an oil film is adsorbed on the mineral surface, but there the analogy ceases. As soon as the mercury comes in contact with the gold, it begins to diffuse into it, forming an intermetallic compound, whereas the oil does not diffuse into the mineral. The gold is also slightly soluble in the excess of mercury present (as shown by the references already cited), whereas the mineral is not soluble in the oil.

Comparing the use of a film of mercury on a copper plate, for the purpose of permitting gold particles in a quietly-flowing pulp of crushed ore to pass beneath the mercury surface and thus be concentrated, with the use of oil to permit air bubbles to attach themselves to ore particles in a violently agitated as well as flowing pulp, and thus float the ore particles, one may say that they are entirely different or the same according to which of the many factors that enter into each of these compli-

*'Philosophical Magazine', series 4, Vol. IX, p. 468.

†'Bulletin de la Société Chimique', series 2, Vol. XXX, p. 20.

ated processes one happens to regard as the most significant. It appears therefore that the action between gold-mercury and oil-mineral is the same or is different according to what phase of the problem one is considering; which would seem to be an ideal condition for promoting the discussion that Mr. Dolbear has invited.

THOMAS T. READ.

Washington, December 10.

Revision of the Mining Law

The Editor:

Sir—I have just read, in your issue of October 8, the letter from Robert B. Brinsmade with reference to the revision of the mining law. I found this letter especially interesting and helpful at this time as we are considering the revision of our Philippine mining laws and there is much conflict of opinion among mining men in the Philippines as to whether we should keep to the principles of the American law, that is, freehold tenure with full right to the subsoil and surface or be guided by the well-known, and by some regarded as infamous, regalian doctrine. Most of the American mining men in the Philippines naturally and sincerely believe in the principles of the old American law whereas the law-makers of the Philippines wish to re-assert the regalian doctrine. In the matter of petroleum and coal we have already changed from a freehold to a leasehold system of tenure and have separated the subsoil and surface rights, both in the United States and in the Philippine Islands.

Recently a committee of Government officials acting with the advice of persons engaged in mining in the Philippines drafted a new general mining law. This is a compromise measure as the result of an attempt to harmonize a multitude of conflicting opinions. The chief bone of contention among those interested in this matter is the regalian doctrine just alluded to. This matter has received considerable publicity and notoriety in the columns of the 'Saturday Evening Post' through the facile pen of Mrs. Eleanor Franklin Egan. This excellent writer on Philippine affairs is generally well informed but when she refers to mining laws that assert the regalian doctrine as "stupid legislation" it would seem that she had got into a field of enquiry in which there is room for further study. Inasmuch as she reflects upon the law-makers of some important mining countries, and upon the judgment of some rather eminent authorities in this field, one of whom is Mr. A. C. Veatch, who was delegated by President Roosevelt to study the mining laws of Australasia and who returned a verdict in favor of the leasing system and of the separation of the subsoil and surface rights, it would seem that some objections should be raised to her exposition of the matter. Her further assertion that the regalian principle is un-American does not necessarily condemn it, but it does display a provincial bias on her part. My own stand in this matter is as follows: While agreeing to the regalian doctrine that all the people (literally the King or the State) own the minerals, I am opposed to any idea of confiscation or to

making this principle retroactive with reference to lands already alienated under patent or Torrens title. The general doctrine that the mineral resources are an asset of all of the people, and that they are not for the exclusive use of a few privileged persons, is so thoroughly in accord with the modern trend of opinion as to social relationships that there seems to be no sound argument against it. Of course, the chief difficulty here arises from the fact that the Congress of the United States in the Act of July 1, 1902, did not make a specific statement on this subject, though the presumption is that that body meant to abrogate the regalian principle. Although the Philippine Supreme Court, a majority of whose members were Filipinos, rendered an opinion in favor of it, the final settlement, in my judgment, will rest with the Supreme Court of the United States. It is perfectly clear that under the Jones law the Philippine legislature was given authority by the Congress of the United States to pass such legislation as it deemed advisable having to do with all its internal affairs, and the Philippine legislature has under that authority re-asserted this principle.

I do not intend to occupy valuable space in your paper for a repetition of the many arguments that can be given on both sides of this important mooted question, further than to say that my experience in the Philippines leads me to think that the mining industry has been delayed in its development here as the result of the tying up of many good properties by speculators. Owing to the laxity in enforcement of such regulations as we have, evils of this kind have been allowed to continue that might have been avoided (and there are many ways of evading even the best of regulations). Under a well-administered leasing system legitimate enterprise can go ahead, and by canceling the lease the speculator can be curbed.

The question at issue here far transcends the mining business. It is at the root of most of our social troubles. The lines are being drawn very sharply today between the exponents of exclusive and selfish privilege on the one hand and those who believe in service and the greatest good for the greatest number on the other. It is upon this question that our civilization may sooner or later be broken. If the issue is met wisely and considerably many of our troubles will vanish; if it is not, the consequences are uncertain. In taking this view I wish to give full credit to the industrial pioneers of our great country. Many of them have been large-hearted and considerate of the public weal, but the situation in America and all over the world today is quite different from what it once was. Sooner or later the raw materials of the earth, particularly the important industrial minerals, will be looked upon as public utilities not only within the nation but among the nations. Just as there must be a different allocation of the minerals within the nation, there must be a more equitable disposition of the raw materials among the nations, otherwise it will be futile to discuss ways and means of preventing wars.

WARREN D. SMITH.

Manila, November 7.

CONCENTRATE-PITS AND CANCELAS

Ball-Milling and Flotation at Catemu, Chile—II

Flotation Practice

By F. Benitez

The ore from the Caracoles mine comes from two distinct orebodies, known as the Buenavista and Manto Monstruo. The Buenavista ore is the higher in grade and contains 5.5% copper after sorting at the mine. It is an andesite porphyry, highly altered and shattered. As the deposit is surficial, like the others in the district, most of the minerals have undergone decomposition; almost all the feldspars, the most important components, have been changed to kaolin. Other decomposition products, such as oxides of iron and chlorite, are also present. Some secondary lime, crystallized as calcite, is found in cracks and cavities. This ore is remarkable in that it contains bituminous matter impregnating the gangue. Of the copper minerals present, chalcocite predominates; but chalcopyrite, bornite, chrysocolla, malachite, azurite, and cuprite are also present. Oxidation has penetrated through fissure-planes as far down in the mine as it has been worked—80 metres from the outcrop; but the oxidized minerals occur more plentifully in the first 40 m., after which there is fairly clean sulphide ore. Most of the economic minerals, and especially the sulphides, are disseminated throughout the gangue, and occur as minute

specks, almost invisible to the naked eye. Stringers of chalcocite are also found.

The Manto Monstruo orebody is a bedded bituminous shale assaying 2.5% copper; the ore is dark gray to black, much harder and more compact than that of Buenavista; it contains much calcite, occurring in veinlets; it is heavily impregnated with bitumen, and shows no signs of decomposition. The copper minerals are the same as in the first-class ore, but it contains a greater proportion of chalcopyrite, although chalcocite predominates. Galena and sphalerite are also present. An incomplete analysis of the two ores is as follows:

	Buenavista %	Manto Monstruo %
Copper	5.5	2.5
Silver	51.2	45.2
Iron	4.4	12.5
Lime	5.9	20.7
Alumina	19.7	9.8
Sulphur	2.1	2.1
Lead	0.1	0.2
Magnesia	1.8	6.2

FLotation. Both ores are difficult to treat by flotation, and for the following reasons:

1. The fine state of crystallization of the copper min-

erals in both ores necessitates grinding to at least minus 150-mesh, to free them from the gangue; and even then the copper loss in the tailing is chiefly in the 'chats'.

2. The ore carries, at a minimum, 1% of its copper in the form of oxide; during some months this has risen to 1.8%, or 33% of the total. Sulphidizing is, therefore, necessary to float the oxides; but, even then, most of the copper silicate is lost.

3. The decomposed state of the gangue minerals gives them flotability, which makes it difficult to obtain a high grade of concentrate. The clay particles, on agitation, flocculate and float; the use of a suitable deflocculating modifying agent is necessary, not only to break up the gangue agglomerations and to liberate the entrapped sulphides but also to stiffen the froth and to raise the grade of the concentrate.

4. Calcite, which is an important mineral constituent of the ore, floats with ease.

5. The nature of the gangue is such that it adsorbs oil freely; the carbonaceous matter liberated on grinding does likewise, and floats more readily than do the sulphides. The nature of the oils is, therefore, a question of great importance. The pine-oils, pine-tars, and generally all wood-oils have a much greater tendency than mineral oils to produce flocculation and flotation of the calcite and of the clayey constituents of these ores; if used they must be in small quantities. The wood-tars, especially in conjunction with alkali, produce a dirty, clayey, and barren froth, which is impossible to clean or disintegrate. The nature of the ores precludes the use of wood-oils; selective mineral-oils must be substituted. The consumption of oil is high; with Buenavista ore it never falls below 4½ lb. per ton. This item of cost, which in many flotation plants is but a small percentage of the total,

of weathering can be imagined by those who have had similar experience.

7. The ore from different parts of the mine was often as dissimilar as that from different mines. This necessitated frequent and radical changes in the quantities as well as in the composition of the oil mixtures used.

GRINDING. Theoretically this ore should be ground to minus 150-mesh (I. M. M.), for it is 'chatty' even beyond that mesh. In practice it was found impossible to carry crushing to that degree, not only because the capacity of the concentrator would have been reduced greatly but also because of the cost; moreover, the net gain was not in proportion to the reduction in the amount of copper in the tailing. The economical or commercial limit of grinding, with the Allis-Chalmers mill, lies between 80- and 100-mesh. It did not pay to go beyond that; it was found more economical to lower the grade of the concentrate to about 25%; it was then possible to float a large amount of 'chatty' middling and to keep the tailing down to a reasonable figure, 0.5% copper.

The influence of fine grinding on recovery is seen clearly in the following slide-machine test:

		Tailing, total copper, %
Ore ground to	60-mesh (I. M. M.)	3.90
" " "	80 "	1.30
" " "	150 "	0.40

Table I gives the average screen analysis of the tailing

TABLE I

	Plus 80-mesh*			Minus 80-mesh		
	Total copper %	Copper oxide %	Copper sulphide %	Total copper %	Copper oxide %	Copper sulphide %
Ferraris	1.91	0.43	1.47	1.13	0.55	0.58
Hardinge	2.04	0.58	1.46	1.06	0.53	0.53

*This and all subsequent meshes are about 10% coarser than the I. M. M. screening. The screens used were French ones, designated by the number of openings per square centimetre. Therefore 80-mesh is equivalent to 70-mesh, I. M. M.; 150-mesh, to 140-mesh, I. M. M.

TABLE II

Average screen analysis for March, April, and June 1920, of concentrate and general tailing, Buenavista ore. Mill: Allis-Chalmers. Sulphidizing practised.

CONCENTRATE				TAILING			
Mesh	% weight		Copper	Insoluble	% weight		Copper
	Cumulative	Individual	%	%	Cumulative	Individual	oxide
Plus 80	4.5	4.5	10.5	51.2	4.5	4.5	0.47
" 100	15.0	10.5	10.4	62.3	15.0	10.5	0.25
" 150	19.7	4.7	14.2	56.6	19.7	4.7	0.25
" 200	30.7	11.0	20.8	46.8	30.7	11.0	0.24
Minus 200	...	69.3	27.8	35.7	...	69.3	0.54

when treating Caracoles ore (Manto Monstruo), has risen to as much as 25% of the total.

6. A large portion of the Caracoles ore that was treated came from dumps at the surface of the mine, where it had lain for three or four years. The prejudicial influences

from Buenavista ore, for three months with the Ferraris and for four months with the Hardinge mill, during 1918 and 1919. Table II shows clearly that fine grinding is necessary, not only to obtain a low tailing but also to produce a high-grade concentrate. The percentage of

TABLE III

Average screen analysis for the month of November 1920 of flotation concentrate and general tailing, Buenavista ore. Sulphidizing with sodium polysulphide practised

CONCENTRATE				TAILING			
Mesh	% weight		Copper	Insoluble	% weight		Copper
	Cumulative	Individual	oxide	%	Cumulative	Individual	oxide
Plus 80	0	0	1.1	1.1	1.17
" 100	6	6	10.1	60.4	7.2	6.1	0.98
" 150	11	5	12.5	55.6	12.3	5.1	0.73
" 200	19	8	16.7	48.8	24.7	12.4	0.21
Minus 200	...	81	27.5	33.4	...	75.3	0.58
Total	100				100.0		
Assay direct			24.3				0.63
Oxide			1.59(?)				0.25(?)

copper as copper oxide in the minus 200-mesh proportion of the tailing is 74%; in the plus 80-mesh product it is only 34.8%, showing clearly a concentration of the oxide in the minus 200-mesh. Almost the whole of the copper oxide lost in the minus 200-mesh was the silicate, or chrysocolla, which would not float even if sulphidized to a black color. The sulphides lost in the minus 200-mesh product were mainly tarnished sulphides and some fine 'chats'.

An incomplete analysis of the concentrate for November 1920 was as follows: copper, 24.3; copper oxide, 1.59; insoluble, 49.6; silica, 33.2; iron, 9.6; magnesia, 1.74; lime, 4.2; alumina, 16.5; sulphur, 9.1; lead, 0.7; zinc, 0.43. The assay of the minus 200-mesh products in concentrate and tailing shows that the oxidized minerals slime easily. The best oxide recovery was obtained from the minus 200-mesh material.

FLOTATION OF THE OXIDIZED MINERALS. Buenavista ore carries, on the average, 1.2% of oxidized copper out of a total of 5.5%, or 22% of the total. The recovery of such was of importance because, no matter how good was the recovery of sulphide, we could not expect a good total recovery without effecting a satisfactory saving of oxidized minerals. These were chiefly malachite, azurite, chrysocolla, and euprite. It was noted that such oxidized minerals, especially the two carbonates, had a tendency to float, even without the aid of any sulphidizing agent. The recovery of the oxides was always above 50%. Undoubtedly, some of the oxides were recovered by the Wilfley table upon which the de-slimed sand tailing from the flotation machine was passed, but the main recovery was made by flotation.

The first attempt at sulphidizing the oxides was made at the La Poza mill, and consisted in feeding sulphuretted hydrogen gas into the agitating-boxes of the M. S. machine. The gas was made by heating Mexican crude petroleum with sulphur at 300°C.; although at times it was produced, often there was a preponderance of something else. After minor explosions and a few cases of poisoning, the experiment was discontinued; not only was the production of the gas difficult, but its delivery to the flotation machine introduced complications. The poisonous nature of the gas was a danger to the Chilean operators who, strange as it may seem, were always keen to smell it. The use of soluble sulphides or polysulphides was inevitable; sodium sulphide was first tried. Although the presence of this compound was found to be beneficial to the flotation of the oxidized minerals, its sulphidizing action was not marked, due probably to its low sulphur content. Consequently, the fused sodium polysulphide of commerce was tried and with more satisfactory results. This reagent had been recommended to us by K. Pettigrew, of the M. S. company, who had tested the ore in London with a view to possible improvements in flotation treatment. At first the polysulphide was added at the mill in lump form and at the rate of 4 lb. per ton of ore, the idea being to grind the ore and the polysulphide together, and where the pulp was thickest.

Assuming that the success of the flotation of oxidized minerals depends on the presence of a coating of artificial sulphide, it was thought that the mill would be the ideal place to add the reagent, because the solution there would be more concentrated than in the flotation machine, where the ratio of water to solids was 4.5 to 1. However, whether that was so or not was never ascertained, because sodium polysulphide, being a strong deflocculator, upset the separation at the classifier and caused more harm than good; it caused this machine to discharge a much finer material. This contradictory behavior of the strongly deflocculated pulp appeared difficult to explain, in view of the fact that flocculation is necessary for settlement or clarification. The polysulphide increased the rate of settlement in the classifier and acted as lime; with 4 lb. added at the mill only minus 200-mesh material would overflow, although the water-to-solid ratio in the classifier was 4.5 to 1, and therefore the classifier should have been discharging at minus 100-mesh. Yet there was no question of the deflocculated state of the pulp. The only explanation was that the polysulphide had no influence on the coarse particles (plus 200-mesh); and that, having broken the kaolin flocules, it allowed the coarse particles to settle more rapidly; or that it affected both sizes differently, causing the coarse to flocculate and settle and the fine to deflocculate and discharge.

The polysulphide was next tried at the first agitating-box of the flotation machine and added there in the form of a supersaturated solution. After many trials it was found desirable to add it from an ordinary paraffin-can, to which a spout was soldered at the bottom. The can was filled to the top with lumps of polysulphide, and a stream of water was added from a hose. In this way the can was always filled with a saturated solution, and the amount of reagent used could be regulated closely by means of the stream of water; the reagent is added at the same rate as it dissolves; if dissolved long before use it was found to have lost its strength.

When the polysulphide was added at the first agitating-box it interfered slightly with the flotation of the sulphides; consequently, it was gradually moved down toward the tail-end of the machine until, after much experimenting, it was found that the best recovery was obtained by adding it at the sixth agitating-box. By this arrangement the first six boxes floated the sulphides; the next three, the oxides; and the last four overflowed as usual and the pulp was returned to the head machine. As already mentioned, sodium polysulphide is a deflocculating agent, also a strong caustic alkali. Its action as a sulphidizing and a deflocculating agent can be discussed together; it was used with the Caracoles ore because of its dual properties. The amount found necessary to deflocculate the pulp and to float the oxides varied from 1½ to 2½ lb. per ton of ore, the average being about 2.2 lb. The quantity added was varied, the amount depending on the nature of the ore; it was regulated by the deflocculating action on the froth, irrespective of the oxide content of the feed; it was found in practice that, gen-

ally, the higher the amount of oxide in the feed the greater was the amount of polysulphide required, the reason being that the oxidized ore came almost exclusively from the outcrop. The decomposed gangue minerals, and especially the clay from this outcrop or weathered ore, agglomerated strongly, and caused a voluminous, watery, and barren froth. This froth was of a dirty reddish-yellow color, caused by the inclusion of much colloidal clay. The same type of froth was produced when the ore contained a large proportion of fine. Wood-tar oils had a tendency to lift such clay flocules, and for this reason their use had to be restricted to small quantities. Moreover, when a wood-tar oil was used as a frother, the pulp was found to be more difficult to deflocculate; the froth that resulted, if an excess of polysulphide was used in an effort to clean it, was like a seum. If, on account of fine material or weathered ore, the froth became voluminous, barren, and of a reddish color, the amount of polysulphide was gradually increased. Slowly the froth would lose its red color and would flow well toward the paddles, losing its tendency to 'hang back' and 'lift' at the back of the boxes. The bubbles could then be seen to be well armored with sulphides, the larger ones being bridged by smaller ones; the resulting froth would be dry, and would break up immediately on falling to the concentrate launder.

When froth was in the condition just described, the pulp was found to be completely deflocculated. The froth from the sixth to the eighth boxes would often be of a distinct grass-green color; and once, when sent to the assay office, returned 13% of oxidized copper in a 17% concentrate. The froth where the polysulphide was added was always shallow, about 2 to 3 in. deep, and often on the point of breaking; on being re-agitated on the succeeding box, however, a good strong froth resulted, which gained in body and volume as it received more agitation. However, if enough polysulphide was added, it was possible to 'kill' the froth entirely, and then re-agitation on the succeeding boxes would not result in a froth. The machine would then take the appearance due to the over-oil effect.

ACTION OF POLYSULPHIDE. Two possible explanations of the action of polysulphide in killing the froth can be advanced. The first and more simple would be that the deflocculation of the pulp had been carried too far, and that the sulphide had been put into the condition of a true suspension. The second would depend on the formation of a soluble soap by the action of the sodium hydroxide contained in the polysulphide upon the oils. Sulman¹ said: "Because of its pronounced adsorption at a water-solid interface, soap is selectively adsorbed at, and consequently detaches oil and grease from, surfaces already oiled. Selective adsorption thus accounts for the detergent properties of soap".

In this connection it will be interesting to mention that caustic soda had been previously tried as a deflocculator, and that its effect was the opposite to that

sought and expected; it increased the volume of the froth and lowered the grade of the concentrate. On one occasion, having no vegetal tar, a local oil produced by the destructive distillation of wood in the making of charcoal, I was compelled to use Mexican crude petroleum and pine-oil. Such a mixture, being composed of two selective oils, one a collector and one a frother, produced too delicate and tender a froth; it was difficult to work, for it lacked the third oil, vegetal tar, which, being a strong frother, gave to the froth the necessary body, volume, and stability. Remembering the effect of caustic soda on a previous froth, of greatly increasing its volume, a concentrated solution of caustic soda was added at the first agitating-box; the froth steadied, and became workable; the results, which previously had been erratic, again became normal. The effect of the caustic soda almost reproduced that of the missing oil. As a general rule it was found that, on all Catému ores, it was not possible to use alkali with a wood-tar; a 'spume' was produced.

USE OF CAUSTIC SODA. Caustic soda was tried on Caracoles ore in an endeavor to deflocculate the pulp; sulphuric acid was useless on account of the calcitic and decomposed nature of the gangue. Although amounts varying from $\frac{1}{2}$ to 10 lb. per ton were tried, no beneficial effect resulted. In his article on colloids, E. E. Free discussed the effect of caustic potash on the degree of flocculation of kaolin suspensions. In the curve showing the degree of flocculation for different concentrations of caustic potash the maximum degree of flocculation is reached with a concentration of from 0.1 to 0.8 gramme per litre. In a pulp with a ratio of water to ore of 4.5 to 1, the quantities required to effect such maximum deflocculation would be from 1 to 8 lb. per ton of ore. These amounts correspond with those recommended by Sulman (1 to 6 lb.). Although in practice the amount used was slowly and carefully increased from $\frac{1}{2}$ to 10 lb., no marked deflocculating effect was noticed, yet the conditions were as similar to those in Free's experiment. In one case it was desired to deflocculate a kaolin suspension with caustic soda, the physical and chemical properties of which are identical with those of caustic potash. Perhaps the negative result was due to the use, at the time, of vegetal tar, which, as we afterward ascertained, was inimical to the alkali.

As fused sodium polysulphide is expensive, costing at Catému P1.05 per pound or P2.30 per ton of ore treated, an endeavor was made to manufacture it locally, by treating a boiling concentrated solution of caustic soda with sulphur.² Several classes of polysulphide were made; although they sulphidized and floated the oxides, their deflocculating action was weak as compared with that of the imported fused article. This polysulphide, which is made by heating sodium sulphate and carbon to 600°C., is strongly caustic and not fully saturated with sulphur; a solution of it will absorb considerably more

¹H. L. Sulman: 'A Contribution to the Study of Flotation'.

²This polysulphide could be made at Catému for half the cost of the imported article or 50 centavos per pound.

sulphur on boiling. Yet the strongly caustic polysulphide gave splendid results as a deflocculator. In every instance the results obtained with the fused polysulphide were far superior to those that resulted by using the home-made article. This may have been due (as Gahl indicates) to the formation of thiosulphates and other oxygen-sulphur compounds.

USE OF SODIUM SILICATE. This modifying agent was also found to deflocculate the Caracoles ore-pulp strongly, 1 to 2 lb. per ton of ore being sufficient; but, as sodium polysulphide had to be used in any case to float the oxidized copper minerals, it was only added in those rare instances in which polysulphide alone was not sufficient to effect the deflocculation of the pulp. It has, however, one advantage over this reagent: it can be used with wood-tars without causing 'spuming'. It is also cheaper, costing only 27 centavos per pound.

FLOTATION OF MANTO MONSTRUO ORE. All that has been said of Buenavista ore applies equally well to the flotation of Manto Monstruo ore, except that it is even more difficult to treat. Owing to the presence of high percentages of calcite and bitumen, it adsorbs oil strongly, and from 5 to 7 lb. per ton is required to effect flotation; 4 lb., an amount that would be considered excessive with many ores, would often not give a froth. From 40 to 60% of the copper in this ore was oxidized (1.0 to 1.5% in a 2.5% head), it was almost impossible to obtain a low-grade tailing, no matter how finely ground. At least 3 lb. of polysulphide was required to float the oxides; but for the deflocculation of the pulp, much larger amounts than this were required.

Sodium silicate was found useful as an additional modifying agent. All the gangue in this ore had a marked tendency to float; in order to obtain a 0.4 to 0.6% tailing, only an 8% concentrate could be secured. During the time that this ore was being tested it was noticed that the mill had developed a muffled noise, and that its capacity was reduced to nil. On opening, it was found that most of the lining and the surface of the balls had become coated with a compound much like plumbago; this was made, it was presumed, by the absorption of the Mexican crude petroleum by the bituminous matter in the ore. This viscous oil, when used with this ore, had a tendency to form this compound, which adhered strongly to iron; for this reason part of the petroleum was replaced by coal-tar. Because of its toughness, low copper content, and unsuitability for flotation, the treatment of this ore was discontinued. The results of a trial run on 650 tons are given in Table IV.

An incomplete analysis of the concentrate is as follows: copper, 13.9; insoluble, 44.8; silica, 37.4; iron, 5.8;

magnesia, 1.40; lime, 9.6; alumina, 9.9; sulphur, 7.5; lead, 2.9; and zinc, 4.3.

The oils used on this test (average figures for the whole of the trial run) were:

M. S. fuel oil	4.00 lb. per ton
Mexican crude petroleum	1.40
Coal tar	0.80
Pine oil	0.20
Total	6.70 lb. per ton

OILS USED WITH CARACOLAS ORE. Almost all the oils on the market, in England and in the United States, were tried on this and the other Catéma ores, both by the company's staff and by outside metallurgists. A successful mixture, which served the purpose well during the early days when trouble and under-capacity in the milling section caused too coarse a feed to go to the flotation machine, consisted of Mexican crude petroleum, vegetal tar, a by-product obtained in the making of wood charcoal, and steam-distilled pine-oil. Mexican crude petroleum was by far the best collector; on account of cheapness—its cost at the plant was only 1 cent (U. S. currency) per pound—it could be used in large quantities (2 to 3 lb. per ton) to saturate the carbonaceous oiled matter in the ore. I do not mean to imply by this that the bitumen in these ores would not adsorb a more selective oil, such as pine-oil, in the presence of Mexican crude petroleum, but that the more selective oil, being also more soluble, went into solution to a greater degree than did the collector. This latter, on account of greater viscosity and non-solubility, was, in turn, adsorbed by the bitumen to a greater degree than was the selective oil. That this surmise was correct was proved later by the fact that when Mexican crude petroleum was used with the bituminous shale, the bitumen and oil were found to mix and coat the balls and lining in the ball-mill.

MEXICAN CRUDE PETROLEUM. Mexican crude petroleum could be used in large quantities because of its non-frothing and collecting qualities. A collector with greater frothing qualities, such as coal-tar, could not be used in larger amounts than 1 to 1½ lb. per ton, otherwise the grade of the concentrate would be lowered considerably. Coal-tar was also found to lift the colloidal clay; it was also three times as expensive as Mexican crude petroleum. Vegetal tar was used as a frother for about 18 months at the Chagres mill, together with the Mexican crude petroleum. It produced a voluminous and tough froth that, though non-selective, served admirably to lift the 'chats' that were left in the feed because of insufficient grinding. The froth made by this oil never broke; a depth of from 12 to 18 in. could be

TABLE IV

carried in the spitzkastens of the flotation machine. In the early days, and before the design of the M. S. machine was improved, a deep froth was a necessity in Catému, because the untrained Chilean operators could not handle a shallow froth (2 to 4 in.), using all the valves in the machine, without overflowing. This oil had a tendency to float much clay; when a little in excess of the right amount was used, the plant was flooded with froth; this was particularly noticeable when the feed contained too much fine material, the so-called primary slime. Steam-distilled pine-oil was used ($\frac{1}{2}$ to $\frac{3}{4}$ lb. per ton) as an auxiliary oil on this ore; it was found that vegetal tar, if used alone, produced a high froth that would adhere to the back of the boxes and that would not flow toward the paddles. Such a froth would

chine or at the mill. The disadvantage in its use was seen in high price and the tendency (when used in amount above 2 lb. per ton) to make a high 'windy' froth. Pine-oil and polysulphide would correct this. Unlike the pine-tars, M. S. fuel-oil does not lift colloidal clay; it works as well with acid as with alkali. After long experimenting it was found that either one of the following mixtures could be used with Buenavista ore and with equally good results:

Collector	{ Mexican crude petroleum, 2 to 3 lb. per ton, or Coal-tar, 1 to 1½ lb. per ton
Frother	Minerals Separation fuel-oil, 2 to 2½ lb. per ton
Auxiliary oils	{ Pine-oil, 0.3 to 0.5 lb. per ton, or Refinery acid, 0.5 to 1.0 lb. per ton, or Pine-tar, 0.1 to 0.2 lb. per ton

Table V gives the results of competitive tests under

TABLE V

	Feed, total copper	Copper oxide	Copper sulphide	Copper concentrate	Total tailing	Sulphide tailing	Oxide tailing	Recovery, total	Recovery, sulphide	Recovery, oxide
	%	%	%	%	%	%	%	%	%	%

'shower'. Pine-oil was used to correct this. Pine-oil was found also to produce good flocculation of the fine sulphides, and was the best oil for floating the oxidized minerals.

VEGETAL TAR. Vegetal tar was unsuitable because the shipments varied considerably in composition; the oil had a tendency to hydrolize, yielding a soluble portion and a viscous portion, the latter being difficult to feed. This oil was expensive, 79 centavos per pound; the discard of large quantities, because of decomposition, was a serious matter; it was replaced by M. S. fuel-oil. This oil, as far as I could ascertain, is a blast-furnace product, to which some cresol or cresylic acid has been added; it is thin and of a reddish-brown color; it has a specific gravity of 0.940 and is a powerful frother and collector. When used alone it would give as good results as in combination with other oils, but it was found economical to use as part of a mixture made up with an equal portion of Mexican crude petroleum. If used alone, 4 to 5 lb. of M. S. fuel-oil had to be used with Buenavista ore to obtain a 25% concentrate from a 5.5% head with a 0.4% tailing, and after grinding to minus 100-mesh (I. M. M.). As M. S. fuel-oil cost, at Catému, 42 centavos per pound, the cost for oil alone would be \$1.90 per ton. By using a half to half mixture of M. S. fuel-oil and Mexican crude petroleum the cost was only 85 centavos per ton of ore—a reduction of nearly 45%.

M. S. fuel-oil was almost an ideal oil for Catému ores. It possessed the essential properties. Being both a frother and a collector, it could be used alone, and this makes for simplicity. It was fairly selective in action, and yet gave a froth that was voluminous, steady, and easy to work, producing both a good grade of concentrate and a clean tailing. Its composition never changed. It was made, I suppose, according to a fixed formula, and did not decompose by either heat or cold. Being a thin oil, it could be fed from any type of feeder; because of its solubility it could be added either at the flotation ma-

chine or at the mill. The disadvantage in its use was seen in high price and the tendency (when used in amount above 2 lb. per ton) to make a high 'windy' froth. Pine-oil and polysulphide would correct this. Unlike the pine-tars, M. S. fuel-oil does not lift colloidal clay; it works as well with acid as with alkali. After long experimenting it was found that either one of the following mixtures could be used with Buenavista ore and with equally good results:

Oils Used in Test No. 1				Cost
M. S. fuel-oil	2.7 lb. per ton			\$1.13
Mexican crude petroleum	3.1 " " "			0.23
Pine-oil	0.4 " " "			0.28
Total	6.2 lb. per ton			\$1.64

M. S. fuel-oil	2.3 lb. per ton			\$0.97
Mexican crude petroleum	1.8 " " "			0.14
Refinery acid-oil	1.2 " " "			0.96
Total	5.3 lb. per ton			\$2.07

CHARACTER OF OIL USED. Although many have argued that the amount and the kind of oil used are of little importance, and "that one oil is about as efficient in flotation as another"³, my experience with the Catému ores leads me to dissent. The quantity and kind of oil used with any ore are of paramount importance in the successful flotation of that ore. Mr. Ruth, however, qualifies his statement by saying that other factors, especially the violence of the agitation, must be adjusted to suit the character of the oil used. But surely it is more economical to secure an oil to suit a particular ore and set of operating factors than to change those factors to suit an oil. I believe that this is what actually happens in practice: the oils are changed to suit the ores and the operating conditions, and not the conditions changed to suit an oil. To change an oil is a simple matter; to change the conditions in a plant that is in operation is far more difficult and costly. My experience with the Catému ores leads me to believe that the difficulties depend more

³Joseph P. Ruth, Jr. 'Eng. & Min. Jour.', Vol. 107.

upon the physical nature of the gangue than on the degree of floatability of the mineral. The troubles with us arose mainly from the decomposed nature of the gangue minerals, as well as from insufficient grinding. All the Catemu orebodies are superficial; and this, coupled with their shattered, broken, and brecciated nature, has enabled oxidation and decomposition to alter greatly their original character. Apart from the finely disseminated or 'chatty' occurrence of the copper minerals, which necessitated fine grinding, the difficulties came mainly from the physical character of the ores; the Caracoles ore adsorbed oil freely, and a thick pulp was produced through which the bubbles with their load of sulphides experienced difficulty in rising. In the Cardenilla ore the trouble was caused by limonite; in the dump-ore from Los Mantos mine, an efflorescence of salts of magnesium and calcium sulphates gave rise to a curdlike precipitate, almost cheese-like in its consistence. K. Pettigrew investigated this, and found the cause of the trouble in the Cardenilla and Los Mantos ores. The use of alkaline defloculators has already been explained.

The important rôle played by the oils in the flotation of the Catemu ores cannot be over-emphasized. Theoretically, oil is not an essential factor in flotation, but air, and any substance like amyl alcohol that will slightly reduce the surface-tension of the water and will allow the formation of a large and strong froth, will do the work; nevertheless, the fact remains that oil is still an essential in flotation plants. A suitable oil and a defloculated pulp are the two essentials for the successful flotation of the Catemu ores, with thorough and violent agitation as an adjunct.

FLOTATION MACHINES. Much has been written about the relative advantages of the flotation machines on the market. Within certain limits (and leaving out such factors as upkeep, capacity, and simplicity of operation), I think that one machine is as good as another, if the pulp is in the proper condition. I believe flotation operators would do well to adopt the advice given by E. D.

text below. The copper minerals include high-grade bornite and chalcopyrite, these are sometimes found together. Azurite, malachite, and chrysocolla are confined mainly to a single bed, the ore from which is smelted direct. The important economic minerals, bornite and chalcopyrite, occur chiefly as fillings in the vesicles of the lava, but also replace the feldspars. The gangue minerals are quartz and feldspars, fresh and unaltered.

A typical analysis of the ore is as follows: copper, 5.1% (after hand-picking); copper oxide, 0.1 to 0.2%; silica, 62.2%; iron, 3.1%; lime, 2.6%; alumina, 20.0%; sulphur, 2.3%. The sulphide ore from this mine is easy and cheap to treat by flotation. The copper minerals break free from the gangue at 40-mesh, and no reagent in addition to the oil is required. A 30% concentrate with a 0.2% tailing can be secured with almost any oil mixture that was tried; only five boxes out of the twelve were run to concentrates, the pulp from the other seven being returned to the head of the machine. Almost the whole of the mineral floated in the first two boxes; the froth produced was always well armored, and had the characteristic dry appearance given only by minerals with a high contact-angle. The gangue, being clean and fresh, was wetted and sank easily and without the help of any modifying agent. However, when an excess of surface-ore was mixed with the current run of sulphide ore, the decomposed gangue minerals acted as 'poison', and fine kaolin flocculated and floated, making the froth voluminous and dirty. From $\frac{1}{2}$ to $\frac{3}{4}$ lb. of sodium silicate added at the head of the machine was sufficient to correct this trouble; this was found to be the best modifying agent for the ore, for strongly alkaline reagents always caused high tailing. For this reason, if the feed contained sufficient oxide to justify the use of sodium polysulphide, this reagent had to be saturated by boiling with sulphur until neutral; if added unsaturated toward the tail-end of the machine, the pulp made alkaline could not be returned to the head of the machine for re-treatment.

Table VI gives the average screen analysis of flotation

Peters in one of his books on copper smelting: "Look after the slag and the matte will look after itself", modifying this to suit flotation, thus: "Look after the gangue and the sulphides will look after themselves".

SALADO. This orebody, which is one of the Catemu group, consists of a series of rhyolitic-lava beds, lying on top of one another and dipping at an angle of 30°. All the beds are mineralized and have well-defined hanging walls, the mineralization occurring chiefly next to the hanging wall and gradually diminishing toward the bed

concentrate and general tailing for a month's run (1250 tons) on Salado ore. An incomplete analysis of the concentrate was as follows: copper, 38.4%; copper oxide, traces; insoluble, 21.8%; silica, 13.4%; iron, 13.9%; magnesia, trace; lime, 0.5%; alumina, 12.0%; sulphur, 20.4%; lead, 0.1%; zinc, 0.2%.

As will be seen from the screen analysis, the sulphide, being much heavier, slimes to a greater degree than did the gangue, the proportion of minus 200-mesh being 70 and 47% in concentrate and tailing, respectively. The

concentrate that was richest in copper was in the two finest meshes, showing that the ore was slightly 'chatty' though not so 'chatty' as were the other Catému ores. This fact was confirmed independently by examination of the tailing under the microscope, which showed that some of the copper sulphide was lost in the 'chats', although the greatest proportion consisted of tarnished sulphides. The most important oxidized copper mineral in this ore was chrysocolla, which occurs mainly as a thin film along small fissure planes or channels. The Witley table, despite the lowness in grade of the feed, never higher than 0.4% copper, made a 5% concentrate on the average. The remainder of the mineral saved by the table consisted mainly of specular iron; this, being almost of the same specific gravity as the bornite and the chalcopyrite, had to be taken off with the latter. The Salado tailing, being more suitable for tabling than Caracoles tailing, always gave a higher ratio of concentration. The table-concentrate, although of low grade, was self-fluxing and could be smelted. An incomplete analysis of the table concentrate obtained from the flotation-machine sand was as follows: copper, 4.9%; insoluble, 2.4%; iron, 59.6%; sulphur, 0.6%.

OIL MIXTURES USED ON SALADO ORE. Almost any mixture consisting of a good collector and a good frother gave satisfactory results but, for obvious reasons, those oils that gave the best recovery at the lowest cost were chosen. Yet in a small plant, such as the Catému, where as many as five different ores might be treated during one month, we had to aim, as far as practicable, to secure a mixture that consisted of no more than three different oils, otherwise confusion in the ordering of the oils would have resulted. Such a mixture consisted of M. S. fuel-oil, steam-distilled pine-oil, and Mexican crude petroleum. During the month of September 1920 the following quantities were used in treating Salado ore:

M. S. fuel-oil	2.00 lb. per ton
Steam-distilled pine-oil	0.26 " " "
Mexican crude petroleum	2.03 " " "

A simpler mixture used on Salado ore consisted of Mexican crude petroleum (2 lb. per ton) as a collector, and local vegetal tar as a frother. This gave good results; but, owing to the extremely variable composition of the vegetal tar, its use was discontinued. On Salado ore, coal-tar could be substituted for Mexican crude petroleum, and only 1 to 1½ lb. per ton was required instead of 3 lb. as with the Mexican crude petroleum. However, as coal-tar costs three times as much as Mexican crude petroleum no advantage was gained by the change.

MINERALS SEPARATION MACHINE. The M. S. machine was the standard 12-box machine. The agitating-boxes were 18 by 18 in., with 12-in. brass agitators of the cruciform pattern. The agitating-boxes were lined with 2-in. local-oak planks, and the wooden lining would last for the treatment of 16,000 tons after reversing the planks once. The brass agitators lasted for the treatment of 8000 tons. The machine was driven by the usual quarter-turn belt-drive from a 40-hp. Allis-Chalmers induction-motor. The power taken by the motor to drive the machine was 30 hp., or 2½ hp. per agitator, when the

agitators were running at 450 r.p.m. The maximum capacity of the machine was 75 tons per day on slime; it was built at a height of 12 ft. from the ground, and rested upon a concrete arch. So firm were the foundations that no vibration could be noticed, even when standing on the machine itself.

The mechanical design of the machine was found to be satisfactory, but the multiple-valve device for regulating the rate of flow of the pulp through the machine gave trouble at first. A valve in each spitzkasten controls the amount of pulp going to the next agitating compartment. The Chilean operators lacked the necessary patience to adjust the level of the pulp in any one box slowly enough, and would not wait for the effect caused by altering a valve on the succeeding box. They wanted to adjust all the boxes at the same time; the inevitable result was that one box would be empty of pulp and the next one would be overflowing. E. D. Pope invented an ingenious device by means of which the pulp in the whole of the machine could be controlled by only 2 valves instead of by the 12 previously required. A slot 26 in. long by 4 in. high was cut in the second, third, fourth, fifth, sixth, and seventh partitions that separate the first eight flotation boxes from one another. The slots in the concentrate boxes were made so that the upper cut was 4 in. below a horizontal line drawn from the overflow point of the box, as in Fig. 1. The first eight boxes when so arranged

FIG. 1

acted as one single box, and a valve at the eighth box regulated the outflow of pulp to the next four, or middling, boxes. The partition between the eighth and ninth boxes was not slotted. The ninth, tenth, and eleventh partitions were slotted; but the upper cut in these slots

FIG. 2

was made, 1 in. below the overflow point, into the concentrate launder, instead of 4 in., as in the concentrate-boxes. A valve at the twelfth spitzkasten regulated the final exit of the pulp from the machine. Thus the first eight spitzkastens making concentrate acted as one box,

and the last four, or overflowing, spitzkastens as another.

The *modus operandi* of the machine on starting was as follows: Suppose that the machine was receiving 1 in. of pulp. As the connecting pipes are 2 in. diameter, all the pulp flowing into the first spitzkasten would be elevated immediately by the second agitator, there being no valve to check it, and discharged into the second spitzkasten; all the pulp arriving at the machine would rapidly pass into the eighth spitzkasten where the valve would check its further flow. The eighth box would fill rapidly, having no outlet, until the pulp reached the level of the slot joining the eighth and seventh spitzkastens, when it would flow into the latter (the seventh), and so successively back again from the eighth to the first box. As soon as froth began to overflow from the machine, the valve at the eighth box would be opened to allow 1 in. of pulp to exit into the other section of the machine (ninth to twelfth boxes); as soon as pulp began to overflow from these the valve at the twelfth box would be opened to allow 1 in. of pulp to discharge from the machine.

The device was criticized; it was argued that it allowed the machine to by-pass; in other words, the pulp could go through the machine without receiving sufficient agitation and treatment. But experience showed that such was not the case. Although the machine has a rated capacity of 75 tons per day, as little as 15 tons, or one-fifth was treated in a day, showing that the pulp could be retained as long as desired. In a machine that is working at full capacity, the slotting of the flotation boxes will show no great advantage, all the valves being almost open; but in machines not working at full capacities the arrangement will be worth while, especially where unskilled labor is employed. Any intelligent operator can learn to work a slotted machine in a shift; much less pulp has overflowed into the concentrate launder since the adoption of such machines at Catému, and one operator suffices, whereas two were required previously.

I wish to say a word of praise for the Dorr classifiers. These machines worked under hard conditions, but they operated well. Not a single shut-down was recorded against them during five years; the only part to be renewed was the roller on which the eccentric works. Credit is due to the Dorr engineers for having developed a machine that has reached such high efficiency. The Frenier sand pumps elevating the pulp to the flotation machine have also done excellent work. These pumps have elevated 50 to 70 tons of sand and 225 to 315 tons of water 22 ft. per 24 hours. The only parts that require renewal are the packing-pieces and the hollow shafts.

SETTLING OF CONCENTRATES. Neither thickener nor filter was used at the Chagres mill. The concentrate was laundered directly to three pits, 3 ft. deep and 340 sq. ft. in area, the fall and a certain amount of raking being sufficient to break up the froth. No trouble was encountered in disposing of flotation concentrate in this manner. The overflow passed through another five pits of the same size, where any remaining slime settled. The water overflow from the last pit was clear, and was

pumped to the main supply tank. The settled concentrate was shoveled into one-ton cars, and spread to dry on a plat with a concrete floor. The moisture in the concentrate when at the smelter was 10% in summer and 20 to 25% in winter.

TAILING DISPOSAL. The tailing was elevated 30 ft. by an 8 in. bucket-elevator, with buckets spaced at 12 in. centres. The belt was of 8 in. balata, traveling at 350 ft. per minute. The tailing was distributed around the dam by means of V-shaped launders with 1 in. round holes drilled at the apex. One man working eight hours per day kept the walls at a height of 3 ft. above the surface of the water. The overflow was clear and was taken out by means of a 3-in. pipe with a right-angle elbow. The water was not re-used because, contrary to expectations, the practice did not decrease the consumption of frothing-oils. My belief is that detrimental salts in the tailing water more than counterbalanced the beneficial effect of those portions of the oils that had gone into solution.

LABOR. The total number of men employed at the Chagres mill is 25, distributed as follows: one foreman, one mechanic, one laborer on the tailing-dam, one man grinding and drying the samples, and three men digging the concentrate in the pits, and spreading it out to dry on the *canchas*. These men work on the day-shift only. On each of the 8-hour shifts there were: one man on the M. S. machine, who also looked after the flotation oils, and acted as shift-boss; one boy on the crusher and ore-elevator; one millman and oiler; one boy for the concentrate pits, for raking the froth, and for looking after the centrifugal pumps; and two men hauling the ore to the mill-bin from the ore-plat. The payroll for the month was P4500, so that the average wage for an 8-hour shift was P6, or about 60 cents, American currency, at the present rate of exchange, which is very nearly P10 per U. S. dollar.

After three years of continuous dealings with Chileans, under trying and adverse conditions, I say with conviction that I would be content to handle no better labor for the rest of my life. The Catému company camps are 'open'; although the introduction of liquor inside the company's premises is prohibited, such prohibition is nominal; nobody troubles to enforce it. The Catému valley is in the heart of an important wine and *chicha* district, where alcoholic beverages are plentiful and cheap. Those who know the Chilean workingman's great failing—his inordinate love of alcohol—will admit that the handling of labor under such conditions is difficult. Yet the men caused little trouble. Chilean laborers when drunk are very quarrelsome, but fortunately they are content to fight among themselves; it is exceptional for an engineer in Chile to get attacked by his own men. Even when mad with drink their behavior toward their chiefs is respectful and considerate. The Chilean *roto* seems to have a profound contempt for life, so that quarrels nearly always end fatally. The greatest inconvenience that the engineer will experience will arise from the reduction in numbers on Mondays and after fête days. 'Sacking' and fines will prove of no avail; the new men

will turn out to be as bad as the discharged ones. I avoided this trouble by giving, to any man who asked for leave, two days per month to go and get thoroughly drunk, provided he supplied a substitute. This arrangement, immoral though it was, worked splendidly; I strongly recommend it to anyone who finds himself in the same predicament, and who is not above making use of it. If Chile were to go 'dry' the efficiency of labor would increase at least 100%. Most of the Chilean working-man's failings can be traced to drink. The *roto* fails to turn out on Mondays because he is unfit for work on account of some drinking orgy on the previous night, not because he is lazy.

The Chilean as a rule is a hard worker, but much better results can be obtained from him if he is put on contract or piece-work. On day's pay he is inclined to be slack. He is a mechanical genius, and there is nothing he loves better than to handle machinery. He likes erecting better than the purely routine work of running engines, and for this reason he is inclined to be careless of details, such as oiling. If properly handled he is docile and willing, but he resents, like most of us, injustice, or being called 'black', which he is not. Because of his independent and proud nature he must be led, not driven; yet he must be ruled with a firm hand, for he is quick to notice and take advantage of weakness. Add to these traits his nomad habits and love of adventure and the Chilean will leave a good job for a reason that, in any other country, men would think nothing of.

Bachelors travel from place to place, not to better themselves but to see life. Perhaps this is due in part to a lack of inducement to stop. Many Chilean *rotos* have no possessions other than what they carry on their backs, so they can travel with freedom. The Chilean working-man is improvident, and saves nothing. He will drink or gamble a month's wages in a single night, and will appear at work on the following or the next day as unconcerned and no sadder than usual. One of his better traits of character is his generosity and his willingness to help an unfortunate comrade. There is no ease of illness, bereavement, or accident that will not find his purse open for the benefit of a mate.

Foreign engineers coming to Chile should possess a knowledge of Spanish. Some make the mistake of thinking that loud shouting will make up for a deficient knowledge of the language. These fail to understand that it is not the men's sense of hearing that is at fault, but their own ideas of Spanish. Besides, the Chilean is apt to take advantage of a foreigner's bad Spanish, and to pretend he does not understand an order, whereas he understands it well. Outbursts of temper are wasted on him; he considers, and not without reason, an exhibition of temper as proof of weakness and unworthy of a man. That is why, in his quarrels and fights, ordinary insults and oaths are conspicuous by their absence. He believes in deeds, not words.

The Chileans as a nation and individually are obedient and law-abiding. Their political evolution has been peaceful; Chilean history only records three revolutions,

which, for the respect for life and private property that all contending parties exercised, together with the high ideals for which they were fought, should be termed civil wars rather than revolutions. In a continent where a revolution is often a cloak for theft, murder, rapine, and brigandage, I think that the peaceful political evolution of Chile deserves to be more widely known and appreciated.

One of the features that will strike a visitor on arriving in Chile will be the lack of gaiety and enthusiasm of the crowds, even in places of amusement, such as theatres. Only on September 18, the anniversary of Chile's declaration of independence, will the foreigner notice a spark of enthusiasm. For the remainder of the year the people are apparently sorry to be alive. The joy of life seems to be unknown in Chile. The *roto* especially is characterized by his profound sadness and stoic indifference, alike to pain and suffering as to the good things of life. An Englishman, whose phlegm is proverbial, would appear mercurial by comparison with him; with this difference, however: the British phlegm is the product of training and an iron discipline from childhood; that of the *roto* is natural, and inherited from his Araucanian ancestors who, for over a century, kept the flower of the Spanish *tercios* at bay, among the woods and valleys of their country. Perhaps, too, the *roto* acquires his hardihood, cold courage, and fatalism slowly as he grows up to manhood; for, whereas the Araucanians used to kill their defective offspring, in Chile today the law of the survival of the fittest rules inexorably and only allows the strongest to reach manhood. Over 50% of the children born are said to die under one year of age. No wonder then, that those who survive are strong, and will look upon the ordinary happenings of life as things of no moment.

The houses (though it is a misnomer to call four walls a house) where Chilean laborers live are often worse than pig-sties; they are unfit for human habitation. Sanitation is conspicuous by its absence; medical attention and hospitals are either lacking or deficient. Working conditions are deplorable, and safety-first rules are almost unknown. The number of fatal accidents in Chilean mines and industries is appalling, and among the highest on record. In a country where the people are naturally docile, the attitude between capital and labor should be one of friendly co-operation and goodwill, provided that employers and engineers exercise those qualities of leadership, tact, and sympathetic understanding that one is justified in demanding of them because of their superior education and broader outlook. Unfortunately, strikes are becoming the fashion, although a few years ago they were almost unknown. Some of these are inevitable; they are the result of the change that Chile is undergoing.

American and European engineers make the mistake, especially when new to the country, of comparing Chileans with skilled Americans or Europeans. Such a comparison is unfair; many Chileans in industrial occupations were, until recently, farm laborers; they were unused to anything more complicated than a shovel. I

made the same mistake at first in comparing Chileans with the skilled Cornish miners and millmen whose ancestors had been occupied in the winning of tin for over seventy generations. That Chileans appreciate and will avail themselves of better living conditions can actually be seen at the settlements of the Braden Copper Co., at Chuquibambata, or at any other of the mining towns built by American companies. Let us hope, for the sake of peaceful relations between capital and labor, that other mining and industrial concerns will copy the splendid lead in welfare work so admirably given by American capital in Chile.

TABLE VII
Total Costs for 1920

	Total cost P	Cost per ton P0	Percentage of total cost
Superintendence	8 832.7	0.932	6.6
Labor	36 585.5	3.800	27.1
Flotation	17 504.2	1.850	13.0

TABLE IX
Average results for 1918, 1919, and 1920

	1918	1919	1920
Feed:			
Total copper, per cent.	6.30	5.77	4.70
Copper sulphide, per cent.	5.35	4.08	4.03
Copper oxide, per cent.	0.95	1.09	0.67
Concentrate:			
Total copper, per cent.	27.1	24.0	31.1
Tailing:			
Total copper, per cent.	1.36	1.06	0.51
Copper sulphide, per cent.	0.83	0.59	0.25
Copper oxide, per cent.	0.53	0.47	0.26
Extraction:			
Total	82.4	85.1	90.6
Sulphide	87.3	90.0	94.8
Oxide	54.5	65.1	66.2
Cost per ton, Pesos	11.13	14.34	14.22
Cost per kilogramme of copper received, pesos	0.237	0.298	0.334

During 1920 the cost of concentrating 1 ton of ore was P14.22; the cost of recovering 1 kilogramme of copper was P0.334 or 33.4 centavos.

PROBABLY no branch of the oil industry has been so profitable as the pipe-line companies. These companies are usually engaged exclusively in the transportation of oil at a certain rate per barrel; they avoid all of the hazards of drilling and the refineries' losses due to sudden price changes. Many of the pipe-line systems in the country have been carrying oil for many years and have long since returned the original capital invested.

Device to Prevent Accidents in Hoisting

By J. J. Bourquin

*Many of the largest coal mines of the United States are in Illinois and Indiana. At these mines it is not uncommon to hoist, from a single two-compartment shaft, 3000 to 5000 tons of coal during an eight hour shift. The mines are equipped with the most modern hoisting engines, some of which operate with maximum rope speeds varying from 3500 to 4500 ft. per minute. The hoisting engine at one mine is equipped with a comparatively simple device which can be applied to any steam hoisting engine, and which eliminates in a large measure the possibilities of accident.

This apparatus is not complicated in its details. The drum of the hoisting engine is equipped with a band brake that can be operated either by a foot-treadle or by a valve admitting steam to a small steam-cylinder, the piston of which acts on the lever of the foot-treadle. This band-brake and the means for applying it are common to all ordinary steam hoisting engines. A large and powerful electric magnet sets on the floor of the engineer's platform a short distance in front of the engineer's post. A bent lever is pivoted to a fulcrum just back of this magnet; one arm of this lever carries an iron block which is attracted to the magnet whenever the magnet is energized by the closing of an electric switch on the shaft bottom. The other arm of the bent lever is connected by a system of links to the valve that governs the admission of steam to the cylinder operating the band-brake. The controlling device for the throttle valve of the hoisting engine is operatively connected with a piston arranged in a second steam-cylinder to which steam is admitted by a pipe that is tapped into the steam-supply pipe carrying steam to the cylinder that operates the band-brake. The junction of these two pipes is just below the valve that governs the admission of steam to the cylinder operating the band-brake; hence the opening or closing of this valve controls the admission of steam into both cylinders. Whenever the magnet is energized, the iron block on the one arm of the bent lever is attracted to the magnet instantly, the system of links or levers connected to the other arm of the bent lever opens the valve admitting steam to the two cylinders, the band-brake is applied, and the controlling device for the throttle valve moves in the direction to close the throttle valve. Thus the hoist stops instantly.

A knife-switch mounted on the timber which supports the brow-timber between the two compartments of the hoisting-shaft on the shaft bottom is used for governing the electric circuit that energizes the magnet at the hoisting engine. In this position the switch is immediately accessible to the eager should trouble occur on either cage. A plate of insulating material about five inches wide by six inches long is attached to the handle of the switch, and this enables the eager to close the switch by simply striking the plate with his hand.

*Abstract from Reports of Investigations, U. S. Bureau of Mines.

Milling Asbestos Ore in Quebec

By Wynant D. Hubbard

INTRODUCTION. The separation of asbestos fibre from the rock in which it occurs is an art differing in almost every essential from the common practice of mineral separation. To separate the fibre without breaking it requires machinery and processes that are used in no other mining industry.

Crysotile asbestos is found in veins of compact crystals, of the composition $H_4Mg_3Si_2O_{10}$, in most cases at right angles to the length of the vein. It is also found along planes of movement as a thin and matted coating. The veins, in most cases, do not exceed 2 inches in width, although extreme widths of 3, 4, or even 5 in. have been found. The majority of veins contain a core of magnetic or chromic iron, forming two veins of asbestos, one on each side of the core. This is particularly true of wider veins. To rid the asbestos fibre of these iron minerals is one of the difficulties of milling.

Asbestos is marketed in two well-defined classes, which in turn are subdivided into grades. The first class, or 'crude', is divided into two grades: No. 1 consists of fibre measuring 1 in. or more in length, and No. 2, $\frac{1}{2}$ to 1 in. This 'crude' is produced by hand-cobbing, which consists in knocking off the walls of the vein with a small iron mallet; and, if there be a centre core of iron, the separation of this from the asbestos by further pounding. Considerable gangue adheres to the fibres, but the manufacturers take it in this form.

The second class, or 'fibre', is produced by the milling. Different grades such as 'B', 'C', 'shingle-stock', 'cement-stock', and 'floats' are produced, and are graded and sold in accord with tests to be described later. The care taken to procure such crude asbestos or long fibre may be understood when the enhanced value is considered. When 'B' fibre is selling at, say, \$400 to \$800, 'C' at \$275 to \$400, and 'cement-stock' at \$17.50 to \$30, No. 1 fibre would be worth \$1700 to \$2000 and No. 2, \$1200 to \$1500. The portion of the product of a mine that is 'crude' varies in different localities, but it is not likely to be more than 0.25 to 0.75% of the total.

Milling comprises four main processes: crushing, drying, screening, and the suction of the fibres from the screens, the last process being the real and ultimate separation. These will be studied in detail as found in the mills, which are commonly of the two-section type, that is, comprising a crushing and drying section and a crushing, screening, and suction unit.

THE CRUSHING AND DRYING SECTION. Large crushers are seldom seen in asbestos mills because the type of ore-handling machinery in the pits does not permit the economical handling of large pieces. Jaw-crushers 15 by 30 in. or 24 by 36 in. are common. Gyratory crushers are seldom used as primary breakers. Considerable discussion has arisen over the comparative suitability of

jaw- or gyratory-crushers for primary breaking. Some claim that the angle of nip of a gyratory crusher is such that it injures the fibre; others, equally well informed, claim that the jaw-crusher is as injurious to the fibre. An investigation of the work of both types on asbestos-bearing rock, leads me to the conclusion that jaw-crushers are less injurious to the contained fibre than are gyratories.

Rock fed into a gyratory crusher has a marked tendency to slide upward and jump, an action that is likely to break the fibre. This jumping tendency can be prevented somewhat by choke-feeding, but the regulation of feed to a primary crusher is difficult. Ore in a jaw-crusher does not jump or slide as in a gyratory crusher, because of the corrugations on the crushing-plates and because of the direction in which the crushing force is applied. A jaw-crusher breaks rock almost entirely by a direct squeezing force; a gyratory, as its name connotes, gyrates, and therefore breaks the rock by a twisting motion rather than by a direct squeeze. This twisting motion, however slight, exerts a pulling force on the rock that often results in broken fibres.

Jaw-crushers are also more economical to operate than gyratory crushers unless a large amount of rock is put through the mill. The following table illustrates this point, with crushers suitable for a 700-ton mill:

	Size of receiving capacity, in.	Approximate capacity in 10 hr., crushing to 4 in., tons	Hp.
Jaw	24 by 36	700	50
Gyratory	24 by 84	2100	140

Secondary crushers, however, are usually of the gyratory type. The feed is about 4 in. and this can be regulated so that the crushers are nearly always choke-fed. This prevents a large part of the jumping referred to above. The twisting motion, however, results in a reduction of the grade of fibre. Jaw-crushers could, of course, be used for this secondary work, but a gyratory is more economical to operate from the point of view of power consumption.

	Size of receiving capacity, in.	Approximate capacity in 10 hr., crushing to 2 in., tons	Hp.
Jaw	8 by 14	85	12
Gyratory	8 by 34	200	20

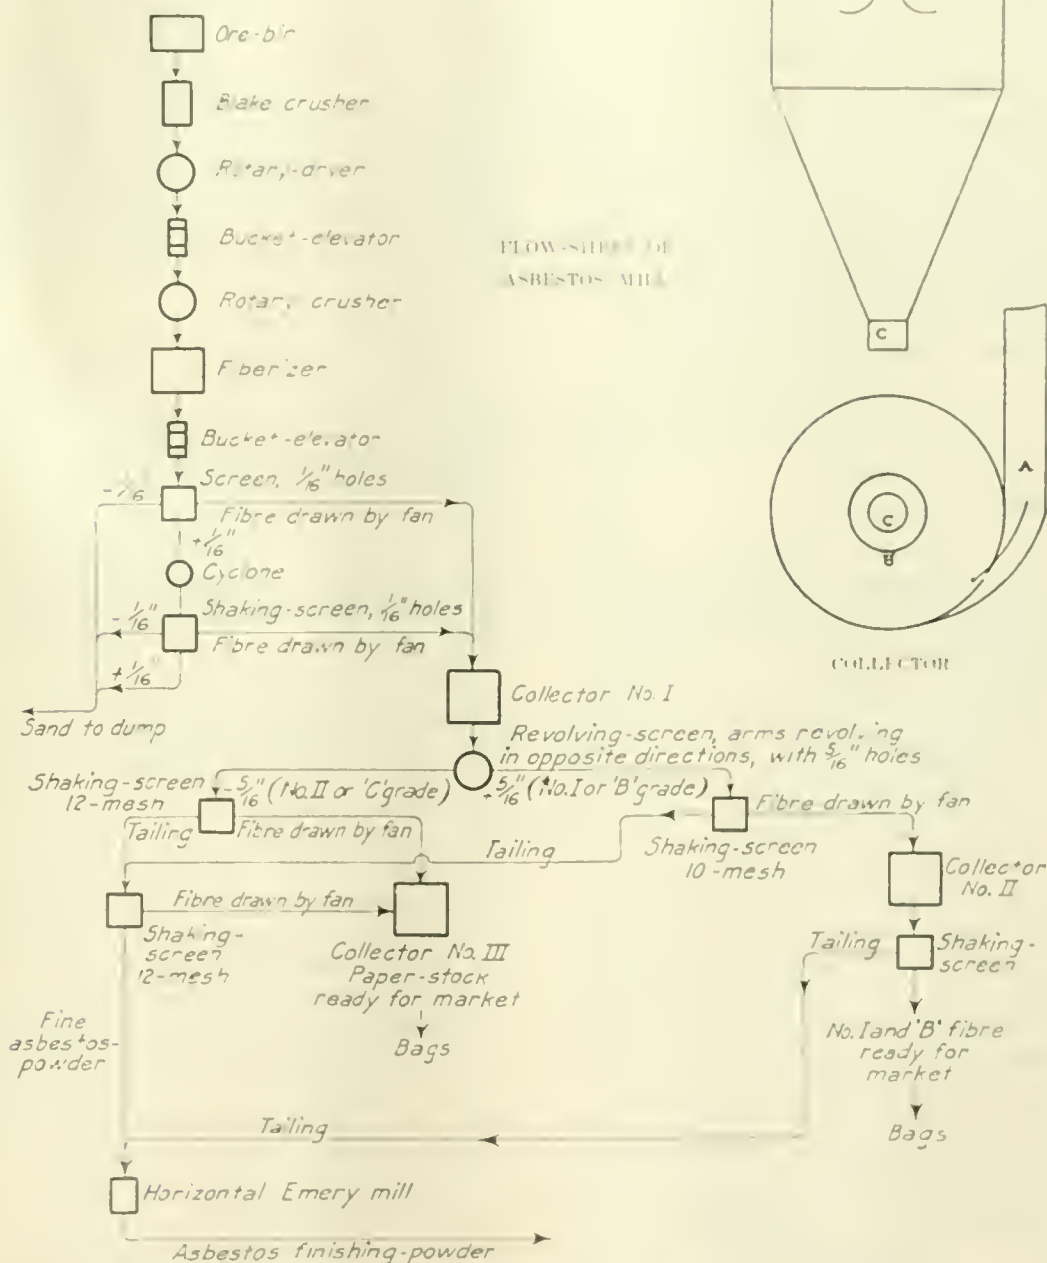

From the above it can be seen that a battery of two jaw-crushers would not equal in capacity that of one gyratory. The gyratory product is also of a more uniform size.

Rotary-crushers were introduced in some of the mills to take the product from the primary breakers. The Butterworth & Low rotary-crusher, which was used generally, is a heavy machine of the coffee-mill type. It

consists of two parts, the upper one for coarse crushing and the lower one for fine crushing. The machine will take feed up to 6 or 7 in. and will reduce it to $\frac{1}{4}$ in. if desired. It has a capacity of 7 to 13 tons per hour and requires 8 to 11 hp. Millmen claimed that this rotary-crusher was efficient; and, because of its drop-base, easy to clean and keep in repair. All the crushing surfaces are of hard chilled iron. It is not now used.

Attention has been given to rolls as secondary crush-

vertical dryer. The single tube horizontal dryers are of the rotating single shell type, with a fire box at one end. Double-shell dryers are coming into general use; their efficiency is much greater. The multiple tube dryer, made by the Campbell company, of Sherbrooke, Quebec,

tial or tower-dryer about 40 ft. high. To prevent the ore from dropping through the dryer too fast, steel rails are placed inside in a criss-cross fashion; the set of rails nearest the top runs at right angles to the set immediately below. This dryer is economical to operate from the point of view of consumption of coal and of repairs.

In tower-dryers, however, there is difficulty in controlling the rate of feed. On warm dry days, rock can be passed through the dryer faster than on wet muggy days; it is profitable to take advantage of this fact. On first consideration, tower-dryers would seem to be far more efficient than those of the horizontal type, and this would be true if a satisfactory method of controlling the feed and the rate of passage of the ore through the dryer could be proposed. Many types have been developed and patented, but in none has this difficulty been overcome. The most satisfactory type so far developed is that in which the speed of the dropping ore is controlled by changing the angle of the baffle-plates. This baffle-plate dryer is economical of coal; the hot air passing upward collects under each plate, keeping it at a high temperature even in winter. The plate-dryer is objected to, however, on the ground that clammy asbestos falling from one baffle to another has a tendency to mat and stick. This can be overcome to a large extent by changing the angle of the plate.

THE CRUSHING, SCREENING, AND SUCTION SECTION. From the secondary crushers the ore is elevated to an intermediate bin, after which it is further reduced. It is at this stage that one of the greatest problems in asbestos milling arises: how to break the dry ore from 2 in. to approximately $\frac{1}{4}$ in. without injuring the fibre. Four different machines are doing this work. The oldest and most common is the Laurie cyclone. In this machine the beaters or impellers are revolved at a maximum speed of 1900 r.p.m. One is revolved clockwise, the opposite one counter-clockwise. The ore drops upon the beater nearest the opening. It is struck by a blade and thrown with great force against the walls of the chamber. It bounces back or drops into the bowl, and is caught and thrown again until it is struck by the beater opposite the feed opening, which is revolving in such a manner that it discharges all material struck by it.

This machine has many defects. Unless it is fed lightly, broken ore accumulates in the bottom of the bowl and is subjected to a beating and grinding action that is injurious to the fibre. Any tramp-iron entering the cyclone causes damage. A nut falling on a beater is thrown against the sides of the machine with sufficient force to break the cast-iron liners. The pieces of the broken liner are in turn hurled around until the whole machine, which is made only of cast-iron plates, is badly damaged, if not smashed. The power necessary to run one of these machines is greatly out of proportion to the amount of work accomplished; 65 hp. should run a crushing machine of greater capacity than 15 tons per hour.

Because of frequent breakage, these Laurie cyclones are extremely expensive to maintain in repair. In all

mills using them, large stocks of beaters, shafts, and other parts are kept on hand because of frequent breakdown.

The second type, found in only a few mills, is the swing-hammer crusher or pulverizer, which finds its chief use in cement-mills, where it is desirable to grind rock to a dust and where the rock contains no mineral that may be injured by such grinding. The semi-circular grizzly that regulates the size of the discharge opening is the main cause of trouble when this machine is used to reduce asbestos rock. The particles that are not broken fine enough to pass the grizzly are dragged across the bars and again carried around the machine. This results in chopping the fibre. The machine is also subject to break-downs from the presence of tramp-iron. Swing-hammer crushers require a large amount of power. When fed with 3-in. rock at the rate of 15 to 20 tons per hour, a swing-hammer pulverizer requires 100 horsepower.

The best machine for this difficult work, and the only one that has been designed solely for asbestos-bearing rock, is the Torrey cyclone—a vertical-type crusher that operates as follows: Ore is fed through the opening and falls on a wearing-plate of manganese-steel. From there it bounces and is caught by the vanes or horizontal impellers, which are revolving at from 1100 to 2000 r.p.m. The ore is hurled from these vanes into manganese-steel jaws. The impact is sufficient to break the rock and liberate the fibre without cutting it. For greater efficiency, another set of vanes revolves below the first, and the hurling and breaking action is repeated.

This machine has great advantages over the other two types. It breaks the rock without injuring the fibre, an action which can be accomplished only by impact breaking. It has a tendency to fluff the liberated fibre, which helps greatly in the succeeding screening processes. Because of the manganese-steel jaws and the wooden casing, which acts as a shock absorber, tramp-iron can do no damage. Moreover, tramp-iron entering the machine does not hit the vanes as they revolve, but slides with them. This has been proved by the passage of bolts, nuts, and bits of drill-steel through the machine without breakage. The vertical shaft hangs from a ball-bearing race, so that little power is required to operate it. A 17-hp. motor will run one Torrey cyclone efficiently for an output of 12 to 15 tons per hour.

The fourth type of machine is the Jumbo or 'fiberizer'. This consists of a horizontal cylinder of steel plate with cast-iron heads, and with liners made of steel plate. The cylinder is in halves, which are hinged together to facilitate opening for cleaning and repair. Through the centre of the cylinder runs a shaft with eight arms of heavy bar-steel, carrying on the ends chilled-iron beaters, the faces of which are at such an angle that the material fed into the machine is driven to the discharge-end as the shaft and arms are rotated. The shaft is geared to make about 300 r.p.m. This machine, made by the Jenckes Machine Co., of Sherbrooke, is used in a number of mills, and gives satisfaction. Less attrition results than with

CYCLONE FIBRIZER, MANUFACTURED BY THE LAURIE ENGINE CO.

by a rotating motor placed beneath. This swift vertical motion (3600 vibrations per minute) keeps the asbestos fibre in suspension above the screen cloth, and allows the sand to pass through quickly. This results in the production of a cleaner grade of fibre and permits the separation of a large tonnage per screen.

The screens are arranged in series of two, each of the same mesh (see flow sheet). Three series are usually used, the first two being 10 by 10 mesh, the second 12 by 12, and the third 16 by 16. The undersize from the first series of screens goes to the second series, and so on.

The fibre in the material that comes from the top of each screen is sucked up through pipes by powerful fans. These suckers are adjusted by the tightening or loosening of a nut on a long screw fastened at the top to the suckers and at the bottom to the screen. The fibre sucked from the screen passes through pipes to collectors, where the useless dust is extracted. From there

FIBRIZER MANUFACTURED BY THE JENCKES MACHINE CO., SHERBROOKE, QUEBEC

the Laurie machine, but it is not as efficient.

In some mills the tailing is ground to a powder for use in plastering. This is done usually in vertical or horizontal Emery mills of the common direct-running type. The advantages of these mills, in regard to ease of adjustment and low power-consumption, are well known.

The screening of asbestos is another problem. Flat shaking-screens are used in every mill but one. These screens are generally 4 or 6 ft. wide and 10 or 12 ft. long. The material that is fed to the screen is a mixture of asbestos fibres of different lengths, sand, and fine gravel. The screens separate the sand from the fibre. Perforated metal is used in some mills instead of wire-mesh because it is less susceptible to clogging. The horizontal motion of these flat screens, which slides the sand and fibres back and forth on the plates, is not conducive to a clean separation, because the asbestos fibres have a tendency to clog the holes.

A new type of screen, the Mitchell, has recently been tested in the King's mill of the Amalgamated Asbestos Corporation. The tests were successful, and Mitchell screens are being installed. The motion of the Mitchell screen is chiefly a vertical one, the force being exerted

FAN FOR TAKING UP FIBRE FROM SHAKING-SCREEN

it falls to the graders, which are revolving octagonal or hexagonal screens. The undersize goes to the mill floors below for further screening and the oversize passes to the bagging-room. There is a grader for each grade of fibre produced.

The fans that supply the necessary suction are of the usual high-speed type. They require about 50 hp. each. The fibre that comes to the bagging-room is tested every 15 min. The man conducting the tests grabs a sample of about 1 lb. from the piles of fibre and takes it to the testing-room. There it is put in the testing machine, which consists of a set of box-screens about 2 ft. long by 1 ft. wide, and 4 in. deep. There are about three of these boxes, one on top of the other, with a pan at the bottom, the top box having a screen of larger mesh than the one below. The fibre is put in the top screen-box and the three boxes and pan are locked to a mechanical shaking machine, which automatically stops after a run of three minutes. The boxes are then taken out, and the fibre left in each screen is weighed. In this way the fibre is graded. Thus 1 lb. of fibre that has been tested with the result that 1 oz. was left in the first box, 3 oz. in the second, 5 oz. in the third, and 7 oz. in the pan could be called 'fibre 1-3-5-7' test, but is usually sold either as grade 'B' or 'C' or as a product that is known as 'shingle-stock'.

From the above it can be seen that, although the separation of asbestos from rock is a comparatively simple process compared with the treatment of ores of the metals, yet it is one that requires special study and, above all, special machines. It is from this lack of special machines that asbestos milling really suffers. Machines used in entirely different mill processes but that appear adaptable to asbestos milling generally give poor results. The Torrey cyclone is the only machine that has been designed for the purpose; only a few managers have adopted it, but those who have are strong in praise of its work. An engineer who would make a specialty of asbestos mining and milling, giving his attention to the design of a good dryer, good screens, and suckers, or perhaps an entirely different method of fibre separation, perhaps by blowing or by using gravity, would do much for a young and growing industry that greatly needs such help.

Loose-Leaf System for Field-Maps and Notes

By John L. Rich

*The equipment for a system of field-maps and notes that, after several years use, I have found to have many advantages, consists of a 5 by 8-in. clutch binder, preferably hinged only on the front cover and opening along the 5-in. side; one or more loose-leaf binders for 5 by 8-in. paper, punched along the 5-in. side; and a supply of loose-leaf co-ordinate paper. That which I am using

is ruled into $\frac{1}{4}$ -in. squares, but $\frac{1}{10}$ -in. squares would, perhaps, serve as well. The system permits both maps and notes to be carried in the same container—a 5 by 8-in. clutch binder that fits readily into the pocket; it preserves the maps from the wear and soiling to which field-maps are usually subjected; it permits ready cross-reference between maps and notes without burdening the former with reference marks; and both maps and notes may be assembled in permanent loose-leaf binders, and classified and arranged in any way the engineer may desire.

When one of the U. S. Geological Survey topographic sheets is being used as a base-map, the map is first cut into nine sections along the parallels and meridians. These sections fit readily into the note-book. Each section is mounted on a sheet of ruled loose-leaf paper in such a way that the top and left-hand sides coincide with ruled lines on the paper. Glue or rubber cement may be used for mounting. The latter has the advantage that it does not cause buckling and is not affected by water. The sections of the map are designated by an initial letter or abbreviation for the name of the sheet and a number for each of the nine sections, numbered from left to right from the top down. Thus the upper right-hand section of the Atoka sheet would be 'A-3'. The lower left-hand section would be 'A 7'. This designation is placed at the lower right-hand corner of the sheet. On the side margins of the loose-leaf sheets, outside the map, the squares of the cross-section paper are numbered from the top down. Only every fifth number, 1, 5, 10, etc., is actually set down. This furnishes one of the co-ordinates for locating positions on the map. The other is furnished by a 'cover-sheet', which is simply a blank sheet of the co-ordinate paper, along the bottom of which the co-ordinate squares are lettered from left to right, beginning about as far from the left-hand margin as is the left-hand edge of the map.

The sheet carrying the section of the map to be used is placed in the front of the binder, with the cover-sheet over it. The notes may be kept in the back of the binder, together with sections of the map not in immediate use. To make reference to a location on the map it is only necessary to slip the cover-sheet up until its lower edge is on a point desired and is parallel to the lower edge of the map. Then, if the zero of the lettering of the cover-sheet be placed at the left-hand margin of the map, the co-ordinates can be instantly determined. The location is recorded in the notes as 'A 3, 10 j', 'A 7, 26 p', etc. This gives the location to the nearest $\frac{1}{4}$ -in. square without making any mark upon the map. If closer location is necessary, a dot on the map may be used. Even a small dot can readily be found at any time by reference to the co-ordinates of the imaginary square in which it occurs. In the office, the location of any point referred to in the notes can be found instantly, even on an uncut map, by lettering and numbering a card to correspond with the co-ordinates that are used in the field and by using the parallels and meridians as guides for the various sections.

Rock-Drilling Tests in the Tri-State Mining District

By C. R. Forbes

*During the past few years the question of rock-drills, drill-bits, and drill-steel have received much attention, and many improvements have been brought about, both in the design and in the use of such equipment.

Among these improvements the use of smaller changes in gauge between successive pieces of steel has been one of the most important. With the old types of piston-drill,

lurgy, who had had considerable practical experience as miners. The work was done in the Bluebird mine of the O. M. Billharz Mining Co. near Commerce, Oklahoma, and was under the immediate supervision of F. H. Gartung, superintendent for that company.

The kind of data recorded in the tests is shown by the following headings from a specimen data-sheet.

Length of steel	Distance drilled	Time drilling in	Time drilling out	Speed of drilling, in per min.	Gauge		Loss	Air pressure	Character of ground	Condition of used bit	Remarks
					At start	At finish					
.....

gauge-changes of $\frac{1}{4}$ in. or more were often used, necessitating the use of steel of from 3 to $3\frac{1}{2}$ in. diameter to start, when deep holes were to be drilled. As the work of drilling varies almost directly with the quantity of material removed, the use of these large sizes of steel resulted in a great loss of time and energy. Until the development of the Carr bit and the modern double-taper bits, gauge-changes less than $\frac{1}{4}$ in. were deemed impracticable. At the present time many companies throughout the United States are successfully using gauge-changes of $\frac{1}{16}$ in. and in some places changes of only $\frac{1}{32}$ in. are used. Although these small changes require great care and accuracy on the part of the drill-sharpener, both in forging and gauging the steels and in proper heat-treatment, still the cost of this extra work in the drill-shop is more than offset by the increased efficiency of the drilling machines.

Another improvement in drilling practice, which has been brought about recently by several companies, is the use of 1-in. steel in place of $1\frac{1}{4}$ -in. in the large mounted hammer-drills. In the Michigan copper-mining district 1-in. hollow hexagon steel has been used for some time in place of $1\frac{1}{4}$ -in. round steel. This steel is used in drills with anvil-block chucks, requiring no collar or lug on the steel. The Copper Queen mine of the Phelps Dodge Corporation has lately standardized on 1-in. round lugged steel for all machines. The advantage of the smaller cross-section consists in the saving in steel, faster drilling-speeds, and saving in labor on the part of the miner in handling the lighter steel.

In order to find out whether or not these improvements were applicable in the Missouri-Kansas-Oklahoma districts, the Mississippi Valley Experiment Station of the Bureau of Mines, working in co-operation with the Missouri School of Mines, conducted a series of experiments extending over a period of four months, beginning May 1, 1921.

The tests were made by I. F. and J. T. Hodges, senior students from the Missouri School of Mines and Metal-

The first series of tests was made to find out the minimum change of gauge practicable for conditions in this district when using the standard $1\frac{1}{4}$ -in. steel.

A study of the practice in the district indicated that gauge-changes of from $\frac{1}{8}$ to $\frac{1}{4}$ in. were commonly used. Drilling is done almost universally with the mounted type of hammer-drills operated by two men; $1\frac{1}{4}$ -in. round hollow steel is used with 24-in. changes in steel lengths.

In order to insure perfect uniformity in the hardness of the bits, a Sullivan oil-forge with pyrometer-control was used for heating the steel. The critical temperature of the steel was determined, and all bits were hardened by plunging from this temperature. The bits were forged on a Sullivan sharpener. Two types of bits were used, the Sullivan double-flare and the cross-bit, both having the double taper. Bits were forged and hardened by the mine blacksmith and were exceptionally well made and uniformly hardened.

The results of this first series of tests showed an average gauge-loss of 3.32 in. for a 24-in. change of steel. In these tests 64 holes, varying in depth from 3 ft. to 12 ft. and totaling 303.5 ft., were drilled. Three different makes of drills were used. Air pressures of from 60 to 85 lb. per square inch were used in drilling.

These results indicated that changes smaller than $\frac{1}{4}$ in. would be impracticable. However, to verify this, three sets of $1\frac{1}{4}$ -in. steel were made using $\frac{1}{16}$ -in. drop in gauge. The results of these tests indicated that it was possible to use $\frac{1}{16}$ -in. drop in gauge in loose water-course ground; but when a hard boulder or hard ground was encountered, the points wore off quickly and caused trouble in changing to the next steel.

The conclusion from all these tests was that for conditions in this district, when using $1\frac{1}{4}$ -in. hollow steel and a 24-in. change in steel-length a gauge-drop of $\frac{1}{4}$ in. is the smallest practicable. Larger changes than $\frac{1}{4}$ in. are unnecessary, as in no case was the loss greater than $\frac{1}{4}$ in. Under these conditions a starter of $2\frac{1}{2}$ -in. diam. will permit a 16-ft. hole to be bottomed with a steel of $1\frac{1}{2}$ -in. gauge. The 24-in. change in length of steel in general use

*Reports of Investigations, U. S. Bureau of Mines.

in the district is quite satisfactory, as in most ground the steel does not become too dull for efficient drilling in penetrating that distance.

The second series of tests consisted in using 1-in. steel in place of 1½-in. In order to conduct these tests it was necessary to equip one of the standard drills with a special chuck for 1-in. steel. Through the courtesy of the Ingersoll-Rand Co. a special anvil-block chuck for 1-in. hexagonal steel was provided. A simple steel retainer was made at a local shop and attached to the drill. The steel was collared similarly to 'jackhammer' steel. The 1-in. hollow hexagon steel was first tried, because it was the only 1-in. steel available. The use of lugless or collarless steel with anvil-block chucks was thought to be impracticable for this district. The rock is mostly chert or cherty shale. The chert is often much fractured and in some cases along the water-courses is in the form of a loosely cemented breccia. Also the chert varies in hardness. That which is known as the primary or light-colored chert is comparatively soft and brittle and is called 'shelly flint' by the miners. The secondary, or dark-colored chert, is very hard. When drilling a hole which penetrates both kinds of chert the 'shelly flint' will shell-off into the hole and cause much trouble in removing the steel. Along the water-courses small cavities are common. These interfere greatly with drilling, causing a loss of water and accumulation of cuttings behind the bit. Another source of trouble is the dropping of small flint pebbles into the hole behind the bit. These pebbles wedge themselves between the steel and the rock and often cause great difficulty in removing the steel from the hole. A miner frequently spends a great deal more time backing the steel out of the hole than in 'drilling-in'.

In view of these conditions it was decided that 1-in. round lugged steel would be the best section to use. However, as no 1-in. round steel was on hand and sharpener parts were not available for sharpening the 1-in. round steel it was decided to use 1-in. hollow hexagon, which was on hand and could be used immediately. In the meantime parts for the sharpener and a chuck for 1-in. round steel were ordered from the Sullivan Machinery Company.

The results of the tests with 1-in. hexagon steel were most encouraging. Nineteen holes from 4 ft. to 10 ft. deep were drilled, with a total depth of 96.9 ft. The longest steel available for these tests was 10 ft. The starters were 1½-in. diam. and ⅜-in. gauge-changes with 2-ft. changes in steel lengths were used. The drilling was done in different kinds of ground, including the hard flint, water-course, and fractured ground. The drilling speed as compared with previous results with 1½-in. steel was increased about 90%. The greatest advantage of the small steel, however, seemed to be in the ease with which the steel could be removed from the hole. This fact was evident in every test. The ⅜-in. drop in gauge was sufficient except in very hard ground where it was necessary to use two steels of the same length in drilling the 24-in. change. The only disadvantages noted with this steel was in cleaning and loading the holes. In the

fractured ground where the sides of the holes are rough it was sometimes quite difficult to get the powder into the bottom of the holes.

The conclusion from the results of 1-in. hexagon steel was that holes up to 10 ft. in length can be drilled faster and with much less exertion using 1-in. steel, than when using 1½-in. steel.

After considerable delay a quantity of 1-in. round steel was obtained from New York by express. Thirty-eight holes, varying in depth from 4 ft. to 16 ft. and having a total depth of 315.7 ft., were drilled with the 1-in. round steel. The results obtained with this steel were not so good as with the hexagon steel. The chief reason for this was on account of the quality of the steel itself, which was of low carbon content and could not be made hard enough to stand the work. The most careful heat-treated bits wore down in a few inches of drilling. The drilling speed obtained with the 1-in. round steel was no greater than with 1½-in. steel. In making up this steel a 1½-in. starter was used with ⅜-in. gauge-drops, making a 16-ft. steel of 1½-in. gauge. Several 16-ft. holes were drilled in bad water-course ground and much trouble was experienced in removing the steel and in cleaning and loading the holes after the steel was removed. However, it may be stated that much trouble would also have been experienced in the same ground with 1½-in. steel.

In all the tests on 1-in. steel, both with hexagon and round, there was practically no breakage. Also there was apparently no greater wear on the machine-hammer than with the 1½-in. steel.

The possibility of using smaller steel in this district is complicated by the method of mining which requires the drilling of many deep holes, and also by the character of the ground.

The use of deep holes necessitates large starting bits. With 1-in. steel a bit larger than 2-in. diam. is undesirable. This means that a 16-ft. hole must be cleared with a bit not to exceed 2-in. diam., which makes it more difficult to keep the machine lined up and also causes more trouble in cleaning and loading than where holes are collared with larger starters. This is especially true in the 'cavey' water-course ground.

The results of these tests, which are still being continued, should show beyond question the possibilities of 1-in. steel in this district.

Since the completion of these experiments at the Bluebird mine the Bilharz Co. has continued the tests, using 1-in. hexagon steel with 1-in. round lugged shanks, and is successfully drilling and loading holes up to 16 ft. in depth.

CONCLUSIONS. The conclusions are as follows:

1. One-eighth-inch gauge changes and 24-in. changes in steel lengths are best for conditions in this district when using 1½-in. steel.

2. One-inch steel can be used successfully, with the large hammer-drills for drilling holes up to 10 ft. deep, at a considerable saving in time and energy on the part of the miner. Gauge changes of ⅜-in. and changes in steel-lengths of 24-in. can be used with the one-inch steel.

REVIEW OF MINING

DIVIDENDS OF UTAH MINES

Dividends paid by metal-mining companies in Utah during 1921 were the lowest in many years. The banner year was 1918, when slightly over \$29,000,000 was distributed. Companies paying dividends during the current year and the respective amounts follow:

Utah Copper Co.....	\$4,051,225
Silver King Coalition Mines Co.....	364,830
Chief Consolidated Mining Co.....	176,806
Tintic Standard Mining Co.....	117,470
Park-Utah Mining Co.....	50,000
Grand Central Mining Co.....	15,000
Iron Blossom Mining Co.....	25,000
Gold Chain Mining Co.....	10,000
Eureka Hill Mining Co.....	10,000

Grand total\$4,830,331

FLOTATION-OILS FROM WESTERN PINE

In a report on the possible uses of Western pine-turpentine, the Bureau of Chemistry at Washington says that there is a well developed market in the West for crude pine-wood oils for use in the flotation concentration of ores, but that the volume of rich wood obtainable within hauling distance is small. It is probable that single-retort plants, which can be dismantled and moved when necessary, are most suitable for wood distillation in that section, especially in regions remote from railroads. It says such plants might be owned and operated jointly by a number of settlers. Medium-grade stumps, though more plentiful than rich stumps, could be used in a commercial plant only at a cost less than the cost of such wood per cord—\$8.37. The Bureau says the refined pine-oil and the crude oils obtained by distilling Western yellow pine are valuable for ore recovery by flotation and that this is probably the most profitable use to which these products can be put.

CONTEST FOR CONTROL OF ENGELS COPPER CO.

Henry Engels, president of the Engels Copper Co., whose mine and mill are situated in Plumas county, California, has issued a request to the stockholders for their proxies for the forthcoming annual meeting. This request is in opposition to the 'regular' request for proxies made by E. E. Paxton, the company's general manager. Paxton regrets the friction that has been developed, but in justice to the stockholders, will make a formal reply in detail to the charges and statements made in the Engels letter. He declares that the charges are without the least basis in fact. The company has not realized an operating profit during recent months, but the loss has been less than the cost of maintaining the property in an idle condition and the position of the company at the present time is incomparably better than it would be after a period of shut-down, according to Paxton. As to the statements regarding freight-rates and power-contracts, the facts are that the terms of both agreements are highly favorable to the mining company.

In his circular letter to the stockholders of the company, Henry Engels calls attention to the fact that his family and himself have been identified with the mine for more than

45 years, although he adds: "For several years past I have been merely a nominal official representing minority interests in the company". Paxton and his associates control two-thirds of the stock. The letter says that the company has been badly managed; that it "has entered into ill-advised shipping contracts with the railroad whereby we are bound to furnish it with a fixed tonnage of ore for shipment monthly"; that the manager has "entered into a patently bad contract for electric power"; that copper has been produced by the Engels company during a period of low prices and ore wasted when it would have saved the company money to have closed down. He finds fault also with the tearing down of the old mill and the erection of a new one, at a cost, he says, of nearly \$600,000.

WAR MINERALS RELIEF COMMISSION NOTIFIES CLAIMANTS—POSSIBLE COMPLICATIONS

The status of 'war-minerals' appropriations was placed in serious doubt by Speaker Gillette of the House of Representatives when he ruled that the Appropriations Committee has the right to appropriate from a fund different from the one from which normally the payment would be made. This may be construed as authorizing the payment from war-minerals funds of other war-claims, although assurances were given by representatives of the War Department that the war-minerals fund would not be used in payment of a specific War Department claim, in a debate that resulted in the foregoing Speaker's decision. The War Minerals Relief Commission has advised claimants of the recent Act of Congress providing for more liberal interpretation of the Act, and while the Secretary of the Interior has not officially interpreted the Act, it is said hearings may be had in the absence of such interpretation.

MINING CONDITIONS IN SONORA, MEXICO, ARE IMPROVING

Industrial conditions have been greatly depressed on the west coast of Mexico. The suspension of mining, due to the low prices for copper and silver, and the consequent loss of revenue to the State from taxes, has intensified the condition. Now, however, there is greater activity. Mining operations are being resumed and preparations are being made for new development, according to a 'Consular Report'. Nothing definite can be learned as to when the Cananea Copper Co. will resume active operations, but there is the impression that the company will start soon after January 1. Other mines in the vicinity of Cananea are virtually idle. Active operations are being carried on at El Tramado, adjoining the old Socorro mine. At the Mejia mine, in the northern part of the Altar district, new equipment is being installed. The ore at the Mejia is reported to carry from 20 to 180 oz. of silver. The Aztec Mining Co. claims to be expending about \$300,000 on its silver properties near Norla. The San Ignacio and Cabrillo mines, belonging to this company, are considered to be promising. The Cosden Co., of New York, is developing a silver-gold property east of the Altos district, near the Chihuahua State line. Another property is the El Calinan, north of San Blas. The mine has been lying idle and it must be unwatered. It is a silver property. The mines at El Tigre and Nacozari are operating.

H. W. MORSE ADDRESSES LOCAL SECTION OF A. I. M. & M. E.

The monthly meeting of the local section of the A. I. M. & M. E. was held at the Engineers' Club on December 27, being preceded by the usual dinner. F. L. Sizer presided and, after disposing of business matters of minor importance, introduced H. W. Morse, who gave an interesting résumé of the methods available for the treatment of mixed copper ores, that is, ores in which the oxide and sulphide minerals are 'scrambled' and economically inseparable. The majority of the larger porphyry copper properties in the United States mine ore that contains copper in oxide form to the amount of 0.2 to 0.4%; this is lost during a treatment that has been designed and is only applicable for the isolation of sulphides. As a general rule the loss of copper because of the unsuitability of the ore to the method in practice varies from 4 to 7 lb. per ton. Sulphidizing preceding flotation has been proved practicable and successful in some cases, but cannot be advanced as a panacea for the trouble. Dr. Morse then dealt at length with the practice at the Ajo plant of the New Cornelia Copper Co., which he described as a perfected and standardized operation that would probably find wide application elsewhere, in spite of the high first cost of the installation, which amounted to about \$1000 per ton per day. A decision by the Inspiration company was imminent in this connection; the recovery of the oxidized copper in the ore was imperative; it was probable, stated Dr. Morse, that the New Cornelia method would be adopted. The procedure under normal conditions would be to crush to 3-mesh or so, leach in large vats with a dilute solution of sulphuric acid, reduce the ferric iron in the solution in sulphur dioxide towers, and precipitate the copper by electrolysis, which provides a satisfactory and methodical process for the final recovery of the metal in pure form. The residue in the leaching-vats, after adequate washing, would be removed and re-ground to the desired fineness, and treated by either of the approved flotation methods. It is probable that, in the majority of cases, the treatment of the oxidized portion of the ore would be simpler than has been the case at Ajo, where fouling of the solution is unusually noticeable because of the prevalence of deleterious compounds in the ore. Dr. Morse discussed the history and application of other leaching processes, in which either ammonia, sulphur dioxide, or iron salts are used; and dwelt at length on a combination process that has attracted much attention of late. In this it is proposed to grind the mixed sulphide and oxide ore to the fineness necessary for the subsequent flotation of the sulphide minerals, treat the pulp by agitation methods with sulphuric acid to dissolve the oxide copper, add sponge-iron to precipitate the copper so dissolved, and then treat the mixture by a flotation method that would ensure the isolation of the precipitated copper as well as the copper in sulphide form. The Van Arsdale method of precipitating copper from solution at high temperature and pressure by means of sulphur dioxide was described, and attention was drawn to the progress that had been made in connection with heap-leaching. An interesting and informative discussion ensued, in which several of the members took part. In conclusion the chairman mentioned that some dissatisfaction had been expressed at the headquarters in New York at the small amount of material supplied by the San Francisco section for the Institute's publication. Dr. Morse's lecture had been taken down in full and would be sent to New York, where it would eventually appear in 'Mining and Metallurgy'. The meeting terminated with a rising vote of thanks to Dr. Morse.

MINTS ARE COINING SILVER AT RECORD RATES

Silver purchases under the Pittman Act at \$1 per ounce have totaled 80 million ounces, leaving 128 million ounces to be purchased to replace silver dollars previously melted.

Of silver purchased \$72,178,000 have been coined, leaving 25 million ounces of uncoined stock of Pittman Act silver on hand. There has been melted under the Act 270,232,722 silver dollars. The three coinage-mints have been operated during recent months on an overtime basis, coinage being the third largest in our history, 553,868,492 pieces having been coined. Resumption of coinage of silver dollars last February, after a lapse of 17 years, is referred to by Secretary of the Treasury Mellon as "the most notable event of the year". This coinage was from the stock of bullion purchased under the Pittman Act. Silver-dollar coinage will continue on a large scale during the silver re-purchases and will probably overshadow other coinage. The mints have also resumed coinage of gold on a moderate scale. The coinage-mints have been reorganized, new methods of handling bullion and new processes of coinage being introduced, resulting in expansion of coinage capacity and economical and efficient administration of the mint service. The largest amount of coin and bullion on hand at any period since establishment of the mint service is carried in the coinage-mints and the New York assay-office.

COPPER STATISTICS IN THE LAKE SUPERIOR REGION—RESUMPTION EXPECTED

Since April 1, when the Calumet & Hecla and subsidiary mines closed down, only seven properties have been in operation in the Lake region. Refinery production was 39% of normal, including the output of the Calumet smelters. Of the seven properties in operation, only four are producers, Copper Range, Quincy, Mohawk, and Wolverine. The Seneca, Mayflower, and Arcadian companies are engaged in development work.

Production, refined, for the year is placed at 107,000,000 lb. Of this amount, 45,000,000 was produced the first three months, leaving 62,000,000 for the remaining nine months' period of curtailment. The average per month for the nine months was 6,890,000, as compared with 22,500,000 normally. The monthly average was somewhat increased by an enlarged refinery production at the Calumet smelters in the last two months of the year, principally in November. Copper Range, Quincy, and the Stanton mines will finish the year with no more than normal stocks of metal on hand. Calumet & Hecla, however, still has a considerable surplus in spite of a large volume of sales during the year. These stocks are sufficient at least to prolong the period of suspension of mining operations until spring and when production is resumed it probably will be on a basis of not more than 50% at the start.

ESTIMATED VALUE OF MINERAL WEALTH OF FEDERAL LANDS

Secretary of Interior Fall, in his annual report, gives estimated tonnages of coal, oil, phosphate, oil-shale, etc., under public ownership, together with royalties thereon that may be expected to accrue to the Government. The total royalty is \$150,000,000,000, including the following: Ten billion tons of bituminous coal at 10c. royalty, \$1,000,000,000; 30 billion tons sub-bituminous coal at 8c. royalty, \$2,400,000,000; 50 billion tons of lignite at 5c. royalty, \$2,500,000,000; (this does not include coal upon railroad lands, private grounds, and private lands in the public-land States not developed); 700 million barrels of crude-oil at \$2, total \$1,400,000,000, 12½% royalty \$175,000,000; 50 billion barrels shale-oil at \$2, total \$100,000,000,000, 5% royalty \$5,000,000,000; 3½ billion tons phosphate at \$4, \$14,000,000,000, 2% royalty \$280,000,000; 20 million tons potash at \$75, \$1,500,000,000, 2% royalty \$30,000,000; 600 million barrels oil on Indian reservations at \$3, \$1,800,000,000; and one billion tons phosphate at \$4, \$4,000,000,000.

ARIZONA

Globe. Most of the time of the Superior Court during the week preceding Christmas was occupied in hearing testimony in the 'apex' suit of the Iron Cap Copper Co. against the Arizona Commercial Mining Co. Judge Pattee of Tucson was on the bench. Among the exhibits presented by the defendant corporation is an elaborate glass model of the Arizona Commercial mine, with the orebodies outlined in detail, showing the faulting of the veins. This faulting complicates the matter decidedly and may lead to legal determination of issues never before presented to a court. Extralateral rights on mineral in place heretofore generally have been claimed only on continuing as unbroken vein matter. The suit is to quiet title to ores found within the vertical lines of certain Iron Cap claims. Arizona Commer-

been uncovered at the bottom of what is known as the Dorsey winze. This winze extends from the 16th to the 19th level. Development shows that the vein is strong and rich. A second discovery of importance has been made in the lower workings of the mine where an excellent ore shoot has been opened. These two new developments seem to insure the success of the project of opening the old producer.

Edward Rose and Arthur Maule have received returns from the first shipment of sacked quartz from the Julia Rose prospect sent to the Selby smelter. The net weight of the shipment was 2136 lb and the two men say the gold and silver contents were thoroughly satisfactory. A prospect shaft has been sunk to a depth of 75 ft., and at 50 ft drifts are being run.

Iowa Hill.—T. L. Schwab of Iowa Hill has bonded his

Ore Beds at the Smelter at Cananea, Mexico

cial also has sued, but in Massachusetts, seeking injunction against the Iron Cap, on the claim that the latter already has taken from Arizona Commercial orebodies about 200,000 tons of ore, valued at \$3,000,000. This Eastern suit appears to be in suspension until the local suit has been settled. On the stand for two days was Guy N. Bjorge, for several years geologist for the near-by Old Dominion property. He was called by the Arizona Commercial, which also called Albert Burch, of San Francisco; Pat Rose, foreman during the Amster administration; W. S. Sultan, a former superintendent of the mine; H. V. Snell of Globe; and R. H. Boyd, a former superintendent, now with the Copper Queen at Bisbee. Charles S. Smith of Lincoln, Massachusetts, president of the Arizona Commercial company, was present at the hearings. For the Iron Cap, expert testimony was given by Horace V. Winchell, W. H. Willey of Glendora, and R. H. Hunt of Los Angeles.

CALIFORNIA

Grass Valley.—According to J. M. Fulton, general manager for the Idaho-Maryland Mines Co., the Eureka lode has

Truro mine to T. T. Maynard and associates of San Francisco. The mine is on the American river, and a portion of the former river channel lying above the present river bed. A tunnel has already been run to the channel and the new lessees expect to start at once to mine the gravel. The channel is 4000 ft. long. Equipment has been ordered and will be on the ground shortly.

La Grange.—The \$400,000 dredge of the La Grange Gold Dredging Co. was launched on December 19. The boat contained some 300,000 ft. of lumber and more than 200 tons of machinery will be installed. Commencement of operations will mark the resumption of mining on an important scale on the Tuolumne river.

Masonic.—H. C. Barnes, who recently secured control of the Pittsburg-Liberty property, reports a good supply of medium-grade ore in sight, but his plan is to develop shoots of high-grade, as milling facilities are still lacking.—The Gold Anchor, which is under option to S. L. Perini, is showing free gold in a tunnel which is being run to intersect the main vein.

Randsburg.—The new mill of the California Rand Silver company has been in successful operation for two weeks. The mechanical operation of the plant is said to be exceptionally smooth and the recovery by flotation is 94% of the silver; \$10 ore is being milled for the present, but the heads will average between \$15 and \$20 after the first of the year.

Spring Garden.—Important development work is in progress at the Walker mine. Drifts are being run on the sixth level in headings leading both north and south of the main shaft. The drift to the north is being driven to cut the downward extension of the ore-zone which is said to have been proved by drifting and diamond-drilling on the 300-ft. level to be 900 ft. long. The main tunnel is equipped with 35-lb. rails, and an electric trolley locomotive haulage-system. Locomotives which can haul eight cars, capable of holding three tons apiece, are in use. The shrinkage method of stoping is employed. As high as 35,000 to 40,000 tons of copper ore, containing appreciable amounts in gold and silver, are stored in stopes awaiting shipment. The 250-ton mill of the Walker company, which, compared with the size of the orebody, is regarded as a mere experimental plant, is said to make the highest recovery of any oil-flotation establishment in the United States. The ratio of concentration, which is four or five tons of ore to one of concentrate, is regarded as the lowest ratio in the country. Because the mill-product is practically self-fluxing, concentrates of the Walker mill are highly desirable for smelting processes. An aerial tramway, nine miles long, connects the mine and mill with the Western Pacific railroad.

Weaverville.—The Shasta Dredging Co., which is operating a gold-dredge near Gas Point, in Shasta county, this month took an option on 1000 acres of gold-bearing gravel in the neighborhood of Minersville. Prospecting with drills is to be undertaken in the spring to test the ground. Included in the bonded area are the claims of J. E. McLean.

COLORADO

Black Hawk.—A concentrating and amalgamation plant of 50-ton daily capacity has been completed by the Cornucopia Leasing, Mining & Milling Co. on its Treasure Mountain property at the head of Silver creek, $3\frac{1}{2}$ miles from Black Hawk. Ore assaying from \$4 to \$25 per ton has been blocked out above the adit. This is estimated at 35,000 to 50,000 tons; it will be mined to meet mill requirements. The tunnel projected to cut the Reform vein entered the new vein after driving a distance of 900 ft. At the junction of the new vein with the Reform ore assaying \$30 to \$40 per ton was exposed when a cave temporarily stopped work. The Reform vein in the early 90's produced rich ore from surface workings, but the property was idle on account of litigation until about 18 months ago.

Breckenridge.—The find made recently on the Warrior's Mark is holding up; recent assays taken across two feet of ore return 1000 oz. silver per ton. In addition three feet of talc beside the quartz streak assays better than 100 oz. silver.

Creede.—Shipments have been resumed from the Commodore mine.—The Corsair lessees, Comstock & Wells, loaded a carload of \$450 grade recently.—Lessees on the Mollie S. are mining and shipping \$50 ore.—The December output of the New York, operated by Morgan & Sloan, is estimated at better than 250 tons with an average value of \$40 per ton.—The Mid-West Mining Co. has men grading roads and trails to the Resurrection and Mollie S. mines preparatory to hauling in machinery and equipment. A power-plant is to be installed at the Resurrection and grading for the site has been completed.

Cripple Creek.—A bond and lease on the Yellow Bird and adjoining claims on the south-western slope of Gold hill, and a lease on the eighth level of the Rose Nicol mine, Battle mountain, have been secured by the Pisgah Mining & Leasing

Co., a Denver company; work has commenced on both properties with Murray Colgin in charge.

The December production from the Cresson mine, Raven hill, will closely approximate 10,000 tons assaying between \$12 and \$15 per ton. The daily shipments are ranging from 8 to as many as 17 cars daily, the latter number having been billed out one day recently.

Lessees in the Elkton mine are making fair production and about a car per day of mill-ore is sent to the Golden Cycle mill at Colorado Springs.

DeBeque.—Assessment work on oil-shale ground in this section has been completed by the Superior Shale Oil Co. of Des Moines, Iowa, controlling 1680 acres 10 miles from DeBeque on Roan creek, and by J. Emil Nelson, of Minneapolis, who with associates controls 16,320 acres in the Phenol, T.N.T., and North Star groups, on both sides of Roan creek. This shale land is considered as among the most valuable with regard to quantity and quality of the deposits.

Georgetown.—The Gilpin Development Co. has found high-grade ore in sampling the old workings of the Capital mine, a recent test showing better than 6 oz. gold, 58 oz. silver, and 17.60% lead, in a vein at the tunnel-level, opened for a distance of 25 ft. A winze has been started down on the ore.—Gray copper ore containing gold and silver has been opened up on the Bellevue Hudson by the Teagarden lessees. Other lessees are mining and shipping good ore.

Idaho Springs.—The old Treasure Vault mine in Virginia canyon has been taken under bond and lease by a New York syndicate and preparatory work has commenced. New equipment, including a compressor, will be installed and the Treasure Vault tunnel is to be extended under the crest of Seaton mountain.—Workmen are constructing a new flume to the Mattie mine to be completed by the end of January.

IDAHO

Coeur d'Alene.—The Sidney and Nabob Consolidated veins are one and the same, according to Bert N. Sharp, mining engineer, who examined them recently. The vein is 40 ft. wide and contains ore on both sides. The orebody discovered recently in the Nabob lies on the hanging-wall side, the same side as yielded a high-grade lead ore in the Sidney.

Larger rolls and a new ball-mill are being installed at the property of the Sunshine Mining Co. in the Big Creek district. The plant is shut-down while the changes are being made. A new compressor with a capacity of 550 cu. ft. per minute is being installed and the company is putting up a two-bucket tram. The changes in the mill will increase its capacity to 70 tons per day and the tram will enable the company to remove its ores from the No. 3 and 4 levels. This company and the Big Creek Mining Co. are jointly constructing an 11,000-ft. flume to pick up the water used in the concentrators and carry it beyond the intake of the water system of Kellogg.

MICHIGAN

Houghton.—Quincy, It is estimated, will finish the year with a production close to 15,000,000 lb. of copper, as compared with 19,216,070 in 1920. Quincy started to curtail in 1920, owing to the depressed condition of the metal market, and on April 1 of this year made a more drastic curtailment, working on a four-day schedule instead of six. In November there was a return to almost a full-time basis, but forces were not materially increased. During the first three months of the year Quincy produced approximately 4,500,000 lb. Quincy has a wonderful amount of good ground well opened ahead and is in a position to take advantage of marked improvement in the metal market. Both its mills and smelter are modernly equipped, making for the lowest possible costs. The tenor of Quincy 'rock' shows no falling off with depth.

Copper Range, which will produce upward of 30,000,000

lb. this year, is another mine in position to respond quickly if labor is available, to improved market conditions. A particularly pleasing development has been the steady improvement in the character of the ground opened in Trimountain where a heavy program of drifting has been in progress throughout the year. Champion rock continues rich, and while Baltic has shown no improvement the average yield for the three mines for the year should be close to 40 lb. of copper per ton of rock stamped.

Mohawk's production for the year is approximately 14,000,000 lb., while Wolverine's output is about 4,000,000. Mohawk is carrying on a normal program of development work and is producing to the capacity of its mill. Wolverine, in addition to regular mining, is engaged in removing the pillars in the bottom levels of No. 4 shaft.

Of the development properties, Seneca is the most advanced and should become a regular producer in the latter part of 1922. Before this stage is reached a new hoist must be installed at the Seneca shaft. In the meantime drifts are being extended north from all five levels of Seneca, in the

Seneca ore mined 978 tons, billion production, \$31,700.72, giving a yield of \$31.81 per ton of ore; total development work for the month 138 ft. North Moeca in the production by Jones was 1422 tons of ore, assaying \$1.60 per ton; royalty received on this ore was \$476.76, owing to the cold weather, Jones decided to stop mining and hauling until next March. Pleasant Gloster mine not operating. Strawn property—development on this property which is under option, is progressing as rapidly as adverse weather conditions and high altitude will permit.

NEVADA

Austin. General excitement has been aroused by the reported discovery of carnotite in the Cahill mine in the Birch Creek district. Carnotite is said to be exposed also at a depth of 110 ft. in the Nevada Birch Creek group.

Eureka. At the Uncle Sam mine an electric-lighting plant, a four-drill air-compressor, and an assay-plant are being installed. Mine machinery, rails, pipe, and fuel-oil have been received, and shipments of high-grade ore will be

Concentrating and Cyanide Plant of the Deer Trail Mining

direction of Gratiot, and the ground on the whole is described as fully up to the average of the Kearsarge lode.

Arcadian Consolidated has resumed sinking in the New Baltic shaft, which will be sunk to a depth of 1060 ft., from which level a drift will be driven south to connect with the 1050-ft. level of the New Arcadian shaft. This drift will parallel the south drift from the ninth level and provide more exact data of the faulted area lying about 800 ft. from the New Baltic shaft. There is no disturbed area up to that point south of the shaft and none to the north, which gives Arcadian a wide copper shoot on both sides of its New Baltic shaft. The ninth level south drift has cross-cut through the fault and is again in good vein matter going south.

Mayflower, in its new operation on the 1450-ft. level, is getting into fairly good-looking ground to the north, although considerable trap is in evidence. The work here will give a better line on the character of the faulted area, which apparently is centred between this level and the 1700. On the 1700, where trap was found after the south drift had passed through a promising long stretch of mineralized ground, the cross-cut is still in the fault.

Extension of the Calumet & Hecla water-system to the company's subsidiary mines to the north, making possible the draining of wells and all surface water, will help to lower pumping costs by diverting the flow of this water away from the mines. The installation of electric pumps generally in all of the mines will further reduce costs.

MONTANA

Butte.—The Barnes-King Development Co. recently announced production for the month of November as follows:

made during the winter, the ore going to smelters in Salt Lake valley. A mill may be erected in the spring.

Lovelock.—F. G. Stewart and associates of Chicago have purchased the gold mining property of E. T. Walker. Stewart has been at Lovelock for several weeks purchasing machinery and necessary equipment for the erection of a reduction plant upon the property. Ground has been broken and a carload of pipe is now at the property to be laid a distance of 6000 ft. with a 400-ft. elevation. The water will be brought from a well and spring to operate the proposed 20-ton amalgamation plant.

The property involved is known as the Old Hagan Hill, two miles north-west of Rochester in Limerick canyon, and 28 miles north-east of Lovelock. It is proposed to have the plant ready for operation by February 1 with E. P. Walker as superintendent.

The 300-ton mill now under construction at Candelaria for the Candelaria Mining Co. will be in operation by spring, according to C. D. Kaedling, consulting engineer. The Mineral County Powder Co. is now building a high-power line to the mines and the mill; William Dunn, who recently completed the installation of the mill at Simon for the Simon Silver Lead Co., is constructing engineer in charge of the mill.

A large amount of low-grade ore now blocked out in the stopes together with ore on the dumps will furnish the first ore for the mill. The building of the mill is being financed by the Rochester Silver Corporation.

Tonopah.—Three men were killed and a score of men were injured, some possibly fatally, in a fire which on De-

ember 22 totally destroyed The Big Ship, a miners' boarding and lodging house owned by the Tonopah Belmont Development Co. The bodies of the three men found in the ruins were identified as L. A. Ballou, Fred W. Johnson, and M. Angosta. They were found at the bottom of a flight of stairs, indicating that the men were trying to escape. So rapidly did the flames spread that the discoverers of the blaze had no time in which to warn the sleepers. Within an hour after the alarm had been sounded the building, measuring 100 ft. in length, 50 ft. in width, and two stories in height, was leveled by the flames. The value of the building was placed at \$8500; the loss was covered by insurance. The structure had been a landmark in the camp, being built 14 years ago. In 1914 it was purchased by Mrs. Mary Harrington and conducted by her as a boarding and rooming house until the miners' strike last summer. It was purchased by the Belmont company last month and was used to house some of the company's employees. Under the name, The Big Ship, the house was known in every mining camp in the West. It was originally known as the Celtic, but was later re-named by the miners.

Yerington.—Reports are to the effect that the Mason Valley Mines & Smelter Co. is completing arrangements for addition of a silver-lead unit to its Thompson smelter. The new installation, including reverberatory furnaces, a refinery, and other departments, will represent an expenditure of \$500,000 to \$750,000. It is also reported that the company plans to manufacture its own coke from the coal exposed in the Darms property near Coaldale. The coal is stated to be excellent for coking, with a large tonnage indicated.

UTAH

American Fork.—The stockholders of the Pittsburg Consolidated Mining Co., at a recent meeting, ratified a deal whereby the Pittsburg Silver Mining Co., a Delaware corporation, secures a lease and bond on the former company's properties in this district, with the privilege of purchasing for \$150,000. The buyers have had charge of the property since September, and recently completed a tramway to deliver ore to a loading-station in the canyon.

Bingham.—The United States Mining Co. and the Highland Boy Mining Co. have been getting excellent results from the use of wet stoping-drills, according to C. A. Allen, chief inspector for the State Industrial Commission. These machines feed water to the bottom of the hole and keep the drill-cuttings constantly wet. The Chief Consolidated and Tintic Standard companies at Eureka are among the large metal producers who have recently adopted these drills.

Eureka.—Directors of the Tintic Standard Mining Co. have declared a dividend of 5c. per share, payable December 31. This is the same amount paid during the first and second quarters of the year, and will call for the distribution of \$58,735. The grand total of dividends to the close of 1921 is \$1,606,167. The chloridizing plant is now precipitating more than 3000 oz. of silver per day and about 1000 lb. of copper. Gold recovery is negligible, but equipment has been ordered that is expected to improve the extraction of precious metal. A recent report states that the reserves of mill-grade ore total 511,000 tons, averaging \$12.08 per ton of recoverable metal. The extraction of silver averages from 83 to 85%; of copper, from 50 to 62%. The reserves of straight smelting ore are estimated at 343,000 tons, averaging \$34.05 per ton. The total amount of silver in the mine, on the above basis, is 17,000,000 oz. The company has produced \$10,000,000 worth of ore in its brief history, all of which has come from an area 700 ft. wide and 700 ft. long.

Ore production from this district for the week ended December 17 totaled 156 cars, as against 176 cars the preceding week. The Tintic Standard shipped 49 cars; Chief Consolidated, 39; Victoria, 12; Iron Blossom, 10; Eagle & Blue

Hell, 9; Centennial-Eureka, 9; Dragon, 8; Colorado, 5; Mammoth, 3; Emplre Mines, 3; Swansea, 3; Gemini, 3; Bullion-Beck, 2; and Alaska, 1.

Marysvalle.—The Deer Trail Mining Co. is one property in the State that continues to produce its regular tonnage of ore. Two classes of ore are shipped direct to the smelter: (a) gold-silver ore, and (b) lead ore. The lower-grade ore is handled in a mill of 100-ton daily capacity by a combined concentrating and cyanide process. The company employs all told from 125 to 135 men. Mining operations are under the deriction of George W. McCaskell, a brother of Jasper A. McCaskell, general manager, while the mill is in charge of Dwight Wadleigh. Recently a suit was filed against the company by A. H. Baldwin, as receiver for the Denver & Rio Grande railroad, for \$1179 with interest, alleged to be due the railroad company on ore shipped from the plant to Salt Lake Valley smelters. The company is a close corporation, controlled by the Salisbury estate of Salt Lake City.

Ophir.—The St. Clair lease at the Buffalo mine, on Lion hill, recently shipped a carload of ore to a Salt Lake Valley smelter that totaled 55 tons, netting \$32.50 per ton. Assays showed \$2 in gold, 47 oz. silver, and 38% lead.

Park City.—It is reported that 4 ft. of high-grade ore has been uncovered recently in an abandoned drift on the 1300-ft. level at the Ontario mine. No work has been done in that part of the property for some time, but certain indications lead Frank Fleishman, foreman, to do a little prospecting. Results indicate that a large orebody has been found.

Ore shipments during the week ended December 17 totaled 2430 tons, of which the Judge allied companies shipped 1128; Silver King Coalition, \$67; and Ontario, 435. Shipments the previous week totaled 2162 tons.

Soldier Summit.—The American Hydro-Carbon Co. has taken over the claims of the Ozokerite Mining Co. The new company has sunk a shaft, which cut a deposit of ozokerite at a depth of 35 ft. A reduction plant is under construction, and is expected to be ready for operation by spring.

WASHINGTON

Colville.—Silver ore said to run \$500 per ton has been discovered on the C. N. Smith homestead four miles north of the Old Dominion mine. Smith, while building a road, uncovered a stringer four inches wide. He continued digging to a depth of 10 ft., the stringer widening. He secured an assay which showed \$6.60 in silver. He obtained assistance and sunk a shaft 30 ft. At this depth the vein was eight feet wide and he reports it gave an assay of \$500 per ton in silver. The outcrop shows for a quarter of a mile north-east and south-west. At the DeSota mine, recently discovered five miles north, picked samples of ore are said to run as high as \$400 in silver.

Daisy.—The Silver Mountain Mining Co. has cross-cut a vein containing ore that assays as high as \$200 per ton in silver and lead. The vein is said to be 8 ft. wide.

The Silver Mountain mine is one of the old properties in Stevens county, and has been operated by William E. Seelye of Spokane and his brother for 30 years, they having expended \$85,000 of their own money on development. The recent discovery is on the 400-ft. level. The present plans are to erect a concentrator at the mine. Crushing machinery is already in place.

Keller.—Sixty pounds of precipitate from the cyanide plant of the Iron Creek Mining Co. brought \$8 per pound from the smelter at Kellogg. This is the product cyanided from the tailing from the concentrator. No shipment of the concentrate has been made and will not be until the railroads grant more favorable freight-rates. The mill is now entirely enclosed and is working satisfactorily. The plant handles 15 tons per day and the recovery is 87%. The mill-

feed is holding up to about \$20 per ton, and the concentration is about 20 to 1.

BRITISH COLUMBIA

Hudson's Hope. According to R. D. Featherstonhaugh, who for the last five years has been testing the gravels along the Peace and Parsnip rivers, at many points these gravels will run from \$1 to \$6 per cubic yard in gold, together with a small platinum content. Featherstonhaugh is making arrangements for extensive operations next spring by means of clam-shell diggers and drag-line.

Princeton.—For some time the Coalmont Collieries, Ltd., has been dumping a quantity of yellow material, found with the coal, on the waste dumps; recently samples of this mineral were sent to the Department of Mines laboratory, at Ottawa, and to a private firm of analysts, at New York. Re-

operation. The underground tunnel is an interesting structure of three stories, 210 ft. long and 16 ft. wide. The tramway enters the top story where there is a 1-hp gas-turbine engine and a hoist for lifting freight that is to be sent to the mine by the train. The ore bunkers, which have a capacity of 1,000 tons, occupy the middle of the second floor, where there also are offices and apartments for the attendants. The ground floor will be used as a warehouse, there is storage capacity for 1,000 tons of sacked concentrate. There is a 20-hp gas-turbine engine on this floor and an elaborate system of belt-conveyors for loading the concentrate directly on board ships. There has been a heavy fall of snow, which has stopped all mining and prospecting, except at those properties at which arrangements have been made for continuing operations throughout the winter.

Vancouver. As the result of the verdict of the coroner's

ports from both places pronounce the mineral to be a good amber, and in future it will be segregated and a market found for it.

Prince Rupert.—H. S. Munro, general manager for the Granby company, passed through here recently on his way to New York, where he has been called for a consultation with the directors with regard to the future policy of the company. For some time the company has had an experimental concentration plant in operation at Anyox, treating a large reserve of ore that is of too low a grade for direct smelting, and it is understood that it has been demonstrated that this ore may be handled profitably with copper at 15c. per pound. For some time the company has had in contemplation the erection of a 2500-ton concentrator to treat this ore. It is likely that the plant may be started on Munro's return.

Stewart.—The S. S. 'Amur' arrived here on December 3 with a large consignment of machinery for the Premier mine, and it took south the largest consignment of concentrate yet sent from the Premier. The new ore-bunkers are completed, and by the time this is published the tramway will be in

jury on the victims of the Britannia Beach disaster, the Attorney General of British Columbia has entered suit against the superintendent and engineer of the Britannia company, charging them with criminal negligence, and Wilfrid Dion, one of the miners who lost his wife, child, and household effects in the disaster, has entered action for damages. The latter is in the nature of a test case. Other writs have been issued, but these will await the decision of the Dion case.

The Britannia M & S Co. is considering tenders for the structural steel part of the new mill-building. The building will be made of fabricated steel and reinforced concrete, thus obviating the chance of a second conflagration. The Britannia company will commence the re-building of the settlement at once; it will be on higher ground, where there can be no possibility of a recurrence of the flood.

MEXICO

Durango.—Plans for the construction of a mill at its mines in the Perico mountains have been made by the Rosario Mining Co. This company is composed of Americans. It has just taken over some valuable properties in the Victoria district, situated to the west of Santiago Papas-

quiario. These mines yield ore rich in gold and silver.

Three different groups of mining claims, one situated in the Tierra Caliente mountains, another in El Ojo de Agua mountains, and the third in the Laurelos mountains, are being developed by Louis R. Goldbaum of El Paso.

Sahuaripa. Francisco Meneses recently denounced the Los Tajos, contiguous to the Yerba Buena group east of Mulatos. This important group is owned by the Cienigita Copper Co. of Kentucky. Among other claims of this company are the Chipiona and Ostimuris. Meneses has also taken up the 'continuations' of Ostimuris where he has been smelting lead in a reverberatory furnace for some time.—Jake Biebrich, one of the American pioneers in Sonora, has installed a reverberatory at the Columbia mine west of Mina Mexico and plans to use fluxes from the Los Hoyos mine west of Arivechl in the Sahuaripa district. Freight-rates and smelter-treatment charges are so high that many in this neighborhood are resorting to the expedient of smelting their own ores.

The Mina Mexico has been working steadily for some time. The mine is producing some high-grade ore and the flotation plant is treating the second class ore and ore from the old dumps. The ore and concentrate are carried by mules to Nacozari and are shipped to the El Paso smelter.—Charles Smith of Nacozari recently took up the old Santa Rita mine about 8 miles east of Hulsamopa. This mine was worked several centuries ago and has enormous dumps and evidences of a large population at one time. One of the freighters from Santa Rita discovered the Trinidad mine in the year 1750. It is planned to open the mine at once.

Torreón.—It is expected that the re-built smelter of the Penoles Mining Co. at Torreón will be finished and blown-in about January 1. This plant was moved from Penoles, in Durango, and has been much enlarged.

ONTARIO

Beaverhouse Lake.—The Argonaut will erect a mill, plans for which will be prepared early in the new year. Construction will commence in the spring. Hydro-electric power is available from Larder lake.

Cobalt.—During November the Nipissing mined ore of an estimated net value of \$251,253, and shipped bullion from Nipissing and custom ores of an estimated net value of \$71,807. The winze on vein 251 at 63 shaft is down 5 ft. and shows a 3-in. streak assaying 5000 oz.. The Nipissing company has taken an option on 14 silver claims in Township 188 along the Mississauga river, the ultimate consideration involved, if the purchase is carried out, being approximately \$1,000,000.—At the Victory, formerly the Hylands, lateral work at 185 ft. has opened a strong vein.—The Right of Way, which recently went into the hands of a receiver, has been purchased by E. J. Daly of Montreal.

Kirkland Lake.—The Wright-Hargreaves during the third quarter of 1921 treated a total of 12,533 tons and produced \$177,420 in gold, the average recovery for each ton treated being \$14.15.

Porcupine.—Two new veins have been opened in a cross-cut on the 1375-ft. level of the McIntyre, each being about 8 ft wide and carrying \$7 gold per ton. Part of the machinery for the 250-ton mill has arrived. The main shaft is expected to reach the 2000-ft. level in a few days and the management is preparing to start active development of the horizon between the 1500- and 2000-ft. levels.

At the Davidson a new orebody, 5 ft. wide, has been discovered at a vertical depth of 500 ft. by diamond-drilling. Assays of ore from the face of the drift on the 600-ft. level average \$17.66 per ton.

Official figures show that the Dome Mines realized an income of approximately \$644,052 for the third quarter of 1921. The premium on exchange will bring this up to about \$700,000.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Floyd C. Merritt, of San Francisco, is at Los Angeles.

C. B. Bacon, of Berkeley, is at Mokelumne Hill, California.

L. Elmhorn has moved from Jalisco, Mexico, to Colona, Colorado.

H. G. Thiele has returned to Oakland from Dougherty, Oklahoma.

William W. Mein is expected in San Francisco at the end of this week.

K. S. Twitchell is on his way back from Sabugal, Portugal, to New York.

Alexander Leggat, formerly of Butte, Montana, has moved to New York City.

William W. Raymond, recently at El Paso, Texas, is in Chihuahua, Mexico.

F. B. Forbes has returned from the Philippine Islands to Pasadena, California.

McHenry Mosier, who has been at Avalon, California, is now at Morenci, Arizona.

George C. Bennett, formerly at Sardis, British Columbia, has returned to Redding, California.

J. S. Williams, general manager for the Phelps Dodge properties in Mexico, was at Cumpas last week.

Charles G. Yale is at St. Luke's hospital, San Francisco, recovering from a severe illness. He is convalescing satisfactorily.

Charles A. Smith, superintendent of mines for the Ray Consolidated Copper Co. at Ray, Arizona, is spending the holidays at Salt Lake City.

John M. Hayes, formerly treasurer for the Utah Copper Co., has returned to Los Angeles after a month's trip to Panama, Havana, and New York.

W. E. Thorne has returned from the tin-fields of Nigeria, British West Africa, where he has been for a short time on consulting work for Ropp Tin, Ltd., of London.

Alpheus F. Williams, general manager for the De Beers Consolidated Mines, at Kimberley, South Africa, is expected in San Francisco on account of the serious illness of his father, Gardner F. Williams.

J. Nelson Nevius, of Pasadena, has completed examinations of the St. Louis and Consolidated properties at Calico, San Bernardino county, and of the Argus Sterling mine near Darwin, in Inyo county, California.

Obituary

Fredrick C. Alley died at Rosario, in Durango, Mexico, last week. He was the owner of El Carmen and other mining properties, and had been in Mexico for a number of years. He leaves a wife and five children, who had only recently returned to Mexico from El Paso, where they had lived during the revolution.

Edward C. Arnold, general mine foreman for the Federal Lead Co., at Flat River, Missouri, died suddenly at Farmington, Missouri, on December 7. He was a native of Texas and was associated with the Inde Gold Mining Co., in Durango, Mexico, for several years before coming to Flat River in 1913. He was 36 years old.

Charles F. Gleason, age 48, died of apoplexy, at Gazelle, California, on December 10. He was chemist at the Murray smelter of the American Smelting & Refining Co. for five years, and in December 1920 he was transferred to a similar position at the Tacoma plant of the company. He leaves a host of friends in Utah who deeply mourn his untimely death.

EASTERN METAL MARKET

(By wire from New York)

December 26—Copper is quiet and strong. Lead is quiet and firm. Zinc is inactive and easier.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 48.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

STANDARD OIL DIVIDENDS

Standard Oil units have paid \$1,833,008.166 in dividends from 1911 to 1921 inclusive. This is more than 18 times the \$98,438.000 stock of Standard Oil of New Jersey, which owned the various units at dissolution in 1911. Cash dividends aggregated \$967,344.798 of the total since 1911. Stock dividends of \$385,609,023 per value distributed in the same period are now worth \$909,793.308. Adding cash payments to this value, total distributions aggregate \$1,833,008.166, says the Boston News Bureau.

Cash payments this year total \$114,444.292. The record high year was 1920, with \$115,776.703. The smallest cash payment in any of the ten years was 1915, when \$63,461.904 was disbursed. The record year for stock dividends was 1913. The \$81,000,000 par value of stock then distributed has a present market worth of \$79,160,000. Standards Oil of New Jersey's \$60,000,000 par stock dividend now worth \$57,000,000 made up most of 1913's stock payments.

Stock dividends are still in vogue. Last year was the second largest in ten years, stocks of \$18,800,000 par having been distributed. Their present value is \$19,440,000. Standard Oil of Indiana's 1920 stock dividend was the largest 1920 item, its \$748,208.7 par value stock distributed now selling for \$18,400,000. The influence of Federal taxation is evidenced in Standard Oil's stock dividend record. No stock distributions were made in 1918 or 1919, reflecting fear of their being taxable. Following the Supreme Court's decision, holding them not taxable, and the big distributions of 1920.

Below is presented a table showing the aggregate dividends for each year in cash per value of stock and present market value. Also the combined cash and market value of stock dividends for the last ten years.

	Cash dividend	Stock dividend (par value)	Stock dividend (present market value)
1921	\$114,444.292	\$79,160,000	\$194,400,000
1920	115,776.703	58,800,000	193,400,000
1919	105,480,000	104,180,000	193,400,000
1918	90,957,904	35,444,318	126,402,222
1917	98,461,904	7,000,000	105,461,904
1916	63,461,904	7,000,000	70,461,904
1915	63,461,904	7,000,000	70,461,904
1914	107,795,001	81,000,000	188,795,001
1913	61,000,000	81,000,000	142,000,000
1912	61,000,000	81,000,000	142,000,000
Total	\$967,344.798	\$3,856,090.23	\$1,823,435.028

Total cash and market value of stock dividends \$1,823,435.028

The 1913 cash dividend payments were abnormal for that period. This was caused by the distribution of an extra 10% payment by Standard Oil of New Jersey representing money received from former subsidiaries in liquidating loans made them prior to dissolution.

MONEY AND EXCHANGE

Foreign quotations on December 27 are as follows:

	Cable	Demand
Sterling, dollars	4 19 1/2	4 20
Franc, centes	8 12	8 14
Lira, centes	4 35	4 35
Mark, cent	6 55	6 55

Eastern Metal Market

New York, December 21.

A strong optimistic tone pervades all the markets. Although buying has slackened to some extent, prices are firm to higher.

The copper market is temporarily quiet as to actual buying, but prices have advanced.

A moderate business has been done in tin at higher price-levels.

Demand for lead continues steady at firmer prices.

The zinc market has advanced on prospective demand and fundamental conditions.

IRON AND STEEL

Producers of steel are not concerned over the recent slackening in demand, says 'The Iron Age'. They look on it rather as a promise of renewed buying early in the new year, since stocks have been drawn to a low point, following the replenishment movement of the fall months. It is also recognized that, next to the unsettled question of freight-rates, uncertainty as to prices is the chief influence now working on consumers of steel, ensuring a continued policy of careful buying. With the shrinkage in new business has come letting down in mill-shipments. In addition to the inventory season, some buyers are asking the holding up of shipments until after January 1, awaiting the removal of the war-tax on freight-charges.

Railroads are proceeding conservatively in placing rails. The Pennsylvania Railroad, which has considered 150,000 tons for 1922, is inquiring for 100,000 tons. The Rock Island, which still has 13,000 tons unshipped on its 1921 quota, will probably take 30,000 to 40,000 tons for next year. The Chicago Northwestern order is expected to be 10,000 tons.

COPPER

A strong tone, followed by slowly advancing prices, continues to characterize the market for electrolytic copper. Sales have not been as active as recently, but inquiry, particularly for first quarter of 1922, continues a feature. The quieter market is natural in the closing weeks of the year. There has been an advance of about $\frac{1}{4}$ c. in the week so that the minimum for December and early delivery is 13.87 $\frac{1}{4}$ c., delivered, or 13.62 $\frac{1}{4}$ c., New York or refinery, with first quarter quoted firmly at 14c., delivered, and 13.75c., New York or refinery. Prospects for good business after the turn of the year are bright, as judged by the character of the inquiries being received. Resumption of mining operations, which are now on a scale of about 40,000,000 lb. per month, is being actively planned.

TIN

While consumers have not been buyers in the past week, a fairly active business has been quietly done among dealers. The former, however, have been watching developments closely. Aside from the business among dealers, transactions on the New York Metal Exchange have been moderately active. From December 13 to 16 about 200 tons was sold at varying prices, or from 32.50c. for December to March shipment from the East on December 13 to 33.50c. for January shipment on December 16. Yesterday and Monday the edge has been taken off the market and practically nothing has been done. Prices have been hovering between 33 and 34c. for spot Straits with the quotation yesterday and Monday at 33c., New York. The continued high levels for exchange have also been a factor. The London market was about £2 per ton higher yesterday at £171 10s. for spot standard, £173 5s. for future standard, and £172 10s. for spot Straits, with the Singapore price on Monday at £174 10s. Arrivals thus far this month have been 2680 tons with 4315 tons reported afloat.

LEAD

The market continues in its steady course of a full demand, about equal to production, and at unchanged but firm prices. Interest in January delivery is active and the metal is available for that position at December prices. The leading interest continues to quote 4.70c., both New York and St. Louis, with other sellers asking 4.70 to 4.75c., New York, and 4.35 to 4.40c., St. Louis.

ZINC

Inquiry, actual or prospective, for prime Western for first quarter delivery is of fairly large proportions and the effect of this has been to strengthen the market. Quotations are higher at 4.90c., St. Louis, or 5.25c., New York, for December or 30-day delivery, with first quarter at 4.95 to 5c., St. Louis, or 5.35c., New York. Light sales have been made at 4.90c., St. Louis, for early delivery as well as 4.95c. for January. Japan continues a buyer for consumption in Japan. It is interesting to note that the volume of this buying has been so heavy in recent months that zinc exports to Japan to November 1 this year, have been 68% of the total.

ANTIMONY

There is no activity and prices are unchanged at 4.50c. per pound, New York, duty paid, for wholesale lots for early delivery. Jobbing lots are quoted at 4.70 to 4.90 cents.

ALUMINUM

Although the leading producer of virgin metal, 98 to 99% pure, quotes 19c. f.o.b. plant, for wholesale lots for early delivery, it is believed to be meeting the quotations of importers of the same grade of 17 to 18c., New York, duty paid. Demand is light.

ORES

Tungsten: No business is reported and there is consequently no change in prices which are nominal at \$2 per unit for Chinese ores and \$2.50 to \$3 per unit for Bolivian wolframite, depending on quantity, delivery, and like factors.

Molybdenum: Nominal quotations rule in an inactive market at 45 to 50c. per pound of MoS₂ in regular concentrates of 85% MoS₂.

Manganese: There is absolutely no buying demand and quotations for high-grade foreign ore are nominal at 20c. per unit, Atlantic seaboard. Importations for 1921 will probably be close to 400,000 gross tons.

Chrome: In the absence of any demand quotations are nominal at \$20 to \$28 per net ton, c.i.f. Atlantic ports, depending on the grade and other considerations.

FERRO-ALLOYS

Ferro-manganese: The Steel Corporation has apparently booked 1000 tons for first half delivery with a large Ohio consumer at about \$60, delivered. There are inquiries amounting to about 600 tons from three or four consumers. Prices are unchanged at a basis of \$58.35, seaboard, for both British and American alloy, with the corporation's product available at \$60, Pittsburgh or delivered.

Spiegeleisen: Sales of a few carload lots are reported at \$26, furnace, for the 20% grade. There are inquiries for several hundred tons for export, an unusual feature of this market.

Ferro-tungsten: Nominal prices rule at 40 to 45c. per pound of contained tungsten in the domestic alloy with 50c. seaboard asked for the imported.

Ferro-silicon: The 50% alloy is available at \$57 per ton, delivered, and a few sales are reported.

Ferro-chromium: Quotations for standard American alloy, 60 to 70% chromium and 4 to 8% carbon, and the imported alloy are nominal at 11 to 14c. per pound, delivered.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

THE HIGHEST-HEAD REACTION-TURBINES IN THE WORLD

In the hydro-electric industry during the year just closing one of the most important events was the completion and placing in operation of the Kern River No. 3 Plant of the

Part of the Edison company's territory is served by a 50-cycle system and part by a 60-cycle system. The heaviest demand on the former comes at a different time of year from the heaviest demand on the latter system. For this reason it is desirable that the plant be equipped to deliver either

Shop Assembly of One of the 800-Ft. Head Vertical Reaction Turbines Built by the Pelton Water Wheel Co. for the Kern River No. 3 Plant of the Southern California Edison Company

Southern California Edison Co., about 50 miles north of Caliente, California. The main power-house equipment comprises two 16,000-kw. General Electric generators driven by two 22,500-hp. vertical reaction-turbines built by the Pelton Water Wheel Co., of San Francisco. These are the highest-head reaction-turbines in the world, and operate under a head of approximately 800 feet.

50-cycle or 60-cycle energy. Each turbine has therefore been provided with two runners, one to operate at best efficiency at 500 r.p.m., and the other at 600 r.p.m. A special design, developed and patented by the manufacturer, permits removing the lower casing cover and the upper section of the draft-tube from below, these castings being equipped with small car-wheels, secured to permanent brackets. After

being disconnected, each section can readily be lowered to rails set in the concrete floor and pushed out of the way. This arrangement makes it unnecessary to disturb either the generator or the gate mechanism in order to change runners. Change of runners can be made in 20 hours, this time being reckoned from the moment the unit is taken off the line until it is again placed in service.

No storage is available at the plant, and during part of the year the entire flow of the stream is not sufficient for both turbines at full load. To provide for such periods, a cross connection is made between the turbines, and one turbine delivers 60-cycle current on a fluctuating load to the appropriate part of the system. The remaining turbine then uses whatever water remains delivering its power into the 50-cycle system. By means of the cross-connection between the units, the master governor automatically sets the load limit on the other unit so that its guide-vanes at once move to use any water rejected by the master machine on load-decrease or vice versa. The maximum available water supply is thus made to do useful work at the highest possible efficiency.

To provide for seasonal variations in the water supply, such as are caused by melting snow, a device is provided so that a rise in the water level above the penstocks causes the turbine-gates to open wider, and thus take more water, while lowering of the water level has the reverse effect.

The plant was completed and placed in operation during April of the present year, and has been in almost continuous operation since then, a large part of the time at a 10% overload, or an output of 25,000 hp. for each turbine.

WELDING 8-TON POTS BY THE OXY-ACETYLENE PROCESS

A long time ago someone with an aptitude for making phrases coined the saying, "It's easy when you know how". Of course it is not always easy, but knowing how helps a lot.

Some time ago the Bunker Hill & Sullivan company, of Kellogg, Idaho, had twenty-six 8-ton cast-iron melting-pots that had been so badly cracked in service at its smelter that they had either to be scrapped or some method of reclaiming them found. They represented an investment of \$31,200. Their value as scrap would be less than a tenth that amount, from which would have to be deducted the cost of transportation to market and reduction. Naturally the alternative of reclamation was important. Attempts to weld them by the electric-arc process proved failures. The first experiments with gas-welding resulted disappointingly also, but the oxy-acetylene process seemed to offer promise of being ultimately successful, and for this reason the engineering department of one of the large apparatus manufacturers was given an opportunity to work out the problem.

In its every-day application, welding is a comparatively simple operation, in which ordinary skill and judgment are sufficient successfully to perform the work. In extraordinary applications, such as the reclamation of these ponderous pots, it is something more—it becomes an engineering problem for which practical experience and ordinary judgment are not enough. There must be an understanding of the fundamentals of the particular problem and a knowledge of how to devise the best way of dealing with the unusual situation. The engineer in this instance was equal to the emergency. He not only successfully welded several of the pots, which have since been in service for some time, but he conducted the demonstration so that other operators could proceed with the reclamation of the remaining pots. The officials of the Bunker Hill company were so well satisfied with the results obtained that they at once ordered a complete installation of the equipment used, including generators for acetylene, and in future it will be used on work

of this kind and for general welding and cutting at the mine and smelter in making repairs to broken and worn machinery and plant structures.

It should not be concluded, however, that the oxy-acetylene service-engineer accomplished his demonstration without some experimenting to develop the best method of procedure. For example, when he tried to pre-heat the first pot in an improvised charcoal-furnace, he discovered that 26 sacks of charcoal burning at one time around the pot little more than warmed it. It was not until he supplemented this with a blast from an oil and compressed-air line connected with a nearby power-house, and covered the furnace and casting with asbestos paper, that he succeeded in securing the pre-heat necessary to proceed with the welding. The pots had been subjected to such high temperatures in service that a large part of the carbon was burned out as in the grate-bars of furnaces. This made it necessary to bring the pots to a high temperature before beginning to weld, in order to effect a homogeneous weld. Of course the pots were annealed after welding, to restore the original structure.

The welding demonstration described was conducted by one of the service-engineers of the Oxweld Acetylene Co.'s Seattle branch. Since then the Northport Smelter Co., hearing of the success of the work at Kellogg, has ordered Oxweld apparatus especially for the reclamation of melting-pots.

COMMERCIAL PARAGRAPHS

The machine-tool division of Pawlings & Harnischfeger Co., of Milwaukee, has just issued Bulletin 4-F, describing its new horizontal boring, drilling, and milling machine. One of the interesting illustrations included in this bulletin show how all operating levers are concentrated on the saddle. A circle with 20-in. radius includes all these levers, giving a good idea of the compactness and convenience of operation.

The Howe Chain Co., of Muskegon, Michigan, has just prepared a new 100-page catalogue, No. 121, illustrating and describing its complete lines of chains for elevating, conveying, and power-transmission. The catalogue contains full-size illustrations, complete information and data, and price-lists for all standard chains. The company wishes to place a copy of this new book in the hands of any interested party or concern.

The Allis-Chalmers Mfg. Co.'s steam-turbine is of the horizontal re-action type. It embodies the essential designs patented by Sir Charles A. Parsons, together with improvements and additions made by the engineers of this company as found desirable from years of operating experience. In this type of turbine the reduction of the pressure of the steam is subdivided into a great number of steps of small pressure drop, the steam expanding in the moving as well as in the stationary elements. These elements consist of rows of blades alternately stationary and revolving through which the steam flows. Guided by the stationary to the revolving blades, the steam expands continuously throughout the length of the turbine, alternately gaining velocity and imparting it to the revolving element, by impulse as it enters the revolving blades and by reaction as it issues from the revolving blades. There is no sudden change in pressure at any point; the reduction seldom exceeds three pounds at any one row of blades and the steam velocities are, therefore, comparatively low, resulting in long blade life. Allis-Chalmers turbines are built in various styles, depending upon operating conditions and the uses for which the units are intended. Bulletin No. 1119 describes the high-pressure single-cylinder condensing units ranging in size from about 5000 to 15,000 kw., operating at speeds of 1500 to 1800 revolutions per minute.

Our large plant is devoted entirely to the making of crucibles.

A large stock of all sizes—regular and tilting furnace shapes—is constantly on hand. Shipments can be made immediately on receipt of order.

~More Heats Per Crucible Means Lower Cost Per Crucible——

You will get longer life and consequently a greater number of heats from BARTLEY VICTORY B-42 CRUCIBLES because they are made by the Lawton Process.

Every Lawton operation—mixing, forming, shaping, burning, has been worked out exactly and the VICTORY B-42 crucibles thus produced are “proving up” in service every day.

VICTORY B-42 CRUCIBLES are low cost crucibles solely because of the increased number of heats it is possible to get with them. Mines using them do not worry about crucible failures at critical times.

Decide now to cut crucible costs by using BARTLEY VICTORY B-24. Booklet containing data on the use and care of crucibles will be mailed on request.

A Manual of Flotation Processes

By ARTHUR F. TAGGART
181 Pages Illustrated Cloth

This book, in part, counteracts the further spread of false conceptions concerning flotation concentration, by setting forth some of the essential facts that contradict them. It describes the apparatus and methods of testing that will aid investigators in their own researches.

Regular Price\$3.00
Subscription to M. & S. P.\$4.00
Both in Combination\$6.00

Handbook for Field Geologists

By C. W. HAYES
Third Edition, Thoroughly Revised and Enlarged
By SIDNEY PAIGE
116 Pages Illustrated Fabrikoid

This book was written as a sequel to a wide experience in geologic field work in the United States and abroad; it gives, in a convenient way, the data most useful to geologists.

Regular Price\$3.00
Subscription to M. & S. P.\$4.00

Prospector's Field Book and Guide

By H. S. OSBORN
Revised by M. W. von Bernewitz
Flexible Fabrikoid 400 Pages Illustrated

Discusses practical mineralogy, crystallography, the use of the blowpipe in prospecting, surveying and chemical tests in the field. The principal characteristics of certain ore deposits in various parts of the world are briefly discussed; this in addition to general instructions for field work. Also contains a complete glossary of mining and mineralogical terms.

Metallurgy of the Common Metals

By L. S. AUSTIN
Cloth Binding 615 Pages 6 x 9 Illustrated

Radical changes and improvements in the metallurgy of the common metals have made necessary this Fifth Edition, which has been largely re-written to bring it in accord with the latest practice. Underlying principles are clearly set forth, and at the same time the details of methods and of metallurgical equipment, and their cost, are given.

DIXON CRUCIBLES

Since 1827

TRUSTWORTHINESS in a crucible eliminates fear of trouble at critical times. The final step in the clean-up—when your concentrates are melted down—can be handled without fear of failure in DIXON CRUCIBLES.

Proper materials, careful workmanship—plus the experience gained in nearly a century of crucible making—these have made the name DIXON known for crucibles of the highest quality.

Large or small DIXON CRUCIBLES are uniform in composition, construction and performance. You can order them with the assurance of getting a staple article.

Joseph Dixon Crucible Co.

JERSEY CITY, NEW JERSEY, U. S. A.

Pacific Coast Office: . . . 444 Market Street, San Francisco

Booklet 141-A

gives valuable information on the care and use of DIXON Crucibles. A copy will gladly be sent on request.

ONLY FIVE MOVING PARTS

Are required for compressing air in the Jackson Rotary.

It is no wonder that this machine fills a real need at every mine. It's capacity is 180 cu. ft. per minute, at any pressure up to 100 lbs. It is so compact that it can be lowered down even the smallest shafts, and is equally useful for surface work.

This is "Every Mines' Compressor."
Bulletin 180-A tells why. Send for it.

THE JACKSON COMPRESSOR COMPANY, 233 South Cherokee Street, Denver, Colorado

MITCHELL ELECTRIC VIBRATING SCREEN

Less than $\frac{3}{4}$ hp. is required to operate a Mitchell screen, yet it is continually establishing records for large tonnage handled and thoroughness of screening. One Mitchell screen operating uninterruptedly over a period of 18 months handled more than a million tons of material at a cost, including power, labor and screen-cloth expense, of less than one-tenth of a cent per ton.

Write us for full details of Mitchell success.

Second Edition Now Ready

FIRE PREVENTION

and

FIRE PROTECTION

As Applied to Building Construction

By Joseph K. Freitag

1038 Pages

Illustrated

Flexible Binding

Price \$5.00

In this new edition many revisions have been made, to keep the treatment up to date, particularly in regard to approved design, construction and equipment. The means whereby the annual fire loss in the United States may be lessened, through preventive measures and rational methods of building construction, are presented by Mr. Freitag in a thorough, practical and easily-understood manner, for ready reference.

Have You Considered GUNITE For Smelter Use?

The "Cement-Gun" and its sand cement product, GUNITE, is not limited in its use simply to cement and hydrated lime. One of its largest uses is in the field of refractory cements. Note the list of companies who are using it for lining ladles.

American Steel Foundries, Alliance, Ohio
Jones & Laughlin Steel Co., Pittsburgh, Pa.
Buckeye Steel Castings Co., Columbus, O.
National Tube Co., Lorain, O.

MIDVALE

MINE SPECIALTIES

ROLL SHELLS, RING DIES and TIRES

EVERY mill superintendent is familiar with the uniform quality and excellent service obtained for years from Midvale Roll Shells, Ring Dies and Tires made at our Nicetown Plant. Heavy forgings of all kinds are also a specialty.

Send us your inquiries

*Midvale Mining Drill Steels
Midvale Hollow Drill Steel and
Carbon Tool Steels*

A large stock of these well-known steels is carried in San Francisco for immediate shipment. Write our San Francisco office for special stock list.

Midvale Steels are also carried in stock at Chicago, Cleveland, New York, Boston, and Philadelphia.

JUST OUT

A NEW BOOK

The ECONOMICS of PETROLEUM

By Joseph E. Pogue

315 Pages

Illustrated

Cloth

Over 100 Tables

Price \$6.00

THE world-wide interest in Petroleum at the present time makes the publication of this book most timely. It is thorough and interesting throughout, and offers a wide range of information of vast importance to the Petroleum Industry.

Not only will this book appeal to petroleum engineers, geologists, and oil producers, but it will prove invaluable to oil executives, sales managers and salesmen, oil jobbers, manufacturers of automobiles, shale engineers, statisticians, economists, industrial engineers, bankers and financiers, investors in oil shares—in fact, to everyone interested in any way with oil.

A special feature of this book is the large number of engraved charts, which give at a glance accurate figures and facts dealing with production, consumption, prices, costs, etc. The data for these charts summarize all the available, statistical information on oil, and are arranged for immediate reference.

MINING AND SCIENTIFIC PRESS, Date
420 Market Street, San Francisco

Gentlemen: I am enclosing herewith \$6.00 for which send me one copy of 'ECONOMICS OF PETROLEUM', by Joseph E. Pogue.

WRITE FOR A COPY OF OUR New 1922 Catalogue of Technical Books

Contains description and prices of the latest and best books
upon the following subjects:

Assaying
Chemistry
Civil Engineering
Concrete Construction
Cyanidation
Electrical Engineering
Electro-Chemistry
Engines
Geology
Hydraulics

Iron and Steel
Irrigation
Law
Machine Shop and Foundry
Mathematics
Mechanical Engineering
Mechanical Drawing
Metallurgy
Mineralogy
Mining Practice

Miscellaneous Engineering
Ore Deposits
Ore Dressing
Petroleum
Prospecting
Scientific Management
Smelting
Structural Engineering
Surveying
Water Power

If you have a copy of any of our previous catalogues and you have not procured your copy of the New 1922 Catalogue, do so immediately, for many new books that are certain to interest you have been added to our list.

NEW Cleveland POCKET-IN-HEAD Stoppers

Full Pressure Throughout Stroke

Is the reason for the superiority of Cleveland 'Pocket-in-Head' drills. This is made possible in Cleveland Drills alone by the exclusive patented 'Pocket-in-Head' feature.

It means a harder, more uniform blow, with less power consumption. The result is a greater footage drilled at less cost.

Try out a Cleveland Stoper in your own mine and compare the results—They will surprise you.

Taylor Spiral Riveted Pipe

346 Pounds Pressure

Incaoro Mines, near LaPaz, Bolivia, S. A.

"The handling of all this material was particularly severe, as it had to be transferred twice at New York, several times at the Isthmus of Panama, again at Mollendo, and many times more during the inland journey, ending with a haul of 120 miles on the backs of mules. In all, there were more than twenty transfers of each shipment, yet the material was so well packed, and was itself so substantial (particularly the Forged Steel Flanges), that there was no loss by breakage.

"Your pipe and your promptness in shipping, I can only say affords a great favor to anyone in a distant country, and I cannot recommend it too highly.

"Very truly yours,

"(Signed) D. C. BRICKER, Gen. Mgr.,
